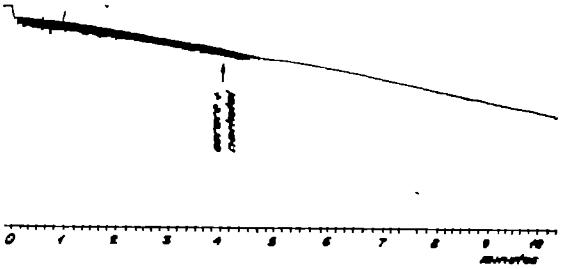
Draper and Whitehead and their co-workers[1] have described a phenomenon which they have called 'diffusion respiration'. In experiments with dogs, they have shown that the blood under certain conditions will be normally oxygenated from the lungs without respiratory movements and without rhythmical changes of pressure in the lungs. They explain this phenomenon as follows. Owing to the affinity of oxygen for hæmoglobin, the amount of oxygen removed from the alveoli during apnea exceeds the amount of carbon dioxide that simultaneously enters from the blood. The pressure within the alveoli is therefore reduced below that of the atmosphere, and a continuous inward movement of the dead-space air and the external atmosphere takes place. Essential conditions, however, for diffusion respiration are a high percentage of oxygen in the lungs and in the dead space, a free airway and an adequate circulation. During the first thirty minutes of diffusion respiration the uptake of oxygen is not reduced. After this time the oxygen consumption and the oxygen content of the blood decrease due, probably, to the Bohr effect produced by retention of carbon dioxide, with respiratory acidosis and low blood *p*H.

Investigations of the phenomenon of diffusion respiration in man have not so far been reported. Some practical observations, however, particularly from work on anæsthetics, afford ground for believing that, under the above-mentioned conditions, in man also enough oxygen can be absorbed in the lungs without respiratory movements. We have therefore studied this question.

Method. During intravenous anæsthesia with 'Narkotal' (a short-acting barbiturate), an air-tight tracheal tube with inflatable cuff was passed. After 10 min. inhalation of 100 per cent oxygen from an anæsthetic machine, the tracheal tube was connected with the expiratory hose of a Krogh's spirometer containing pure oxygen. The absence of measurable positive pressure in the spirometer was thoroughly controlled. The respiratory movements and the oxygen uptake were recorded during about five minutes. After that the subjects were given curare and 'narkotal' in adequate doses for apnea. The periods of apnea were interrupted by re-connecting the tracheal tube to the anæsthetic machine and starting artificial respiration by rhythmic manual compressions of the re-breathing bag. Immediately before, at the end of, and 5 min. after each period of apnea, samples were taken from arterial blood and from lung air (7–11 cm. below the tracheal bifurcation) for analysis of the oxygen and carbon dioxide content. Pulse-rate, blood pressure and electrocardiogram were recorded during the experiments.



Oxygen consumption before and during apnea. The slope of the curve indicates the oxygen consumption (about 0·2 lit./min.), which thus seems independent of respiratory movements

Results. The subjects were kept in apnea for about five minutes, the maximum being 7 min. 20 sec. The oxygen consumption during this time was, as a rule, the same as during the period before the apnea. The oxygen content of the blood did not decrease during the apnea. The carbon dioxide content of the blood and of the lung air, on the other hand, increased during the apnea, but after five minutes of artificial respiration with the aid of the anæsthetic machine the values of the carbon dioxide were normal again. No changes of importance were noticed concerning pulse-rate, blood pressure and electrocardiogram. The subjects remained all the time in a very good condition.

Conclusion. The phenomenon of diffusion respiration, which Draper and Whitehead and their co-workers have demonstrated in animals, seems to occur also in man. Accordingly, it is possible to get sufficient oxygen uptake during short periods of time without either spontaneous or artificial respiratory movements and without rhythmic changes of pressure in the lungs, if the circulation is adequate, and if pure oxygen is supplied through a free air-passage. The accumulation of carbon dioxide prevents prolongation of the apnea for a considerable time.

A complete report of these investigations will be published elsewhere.

Fluorometric Determination of Natural Œstrogens in Urine ; Elimination of Fluorogenic Compounds

THE fluorometric analysis of œstrogens in urine using phosphoric acid for the development of the fluorescence has already been described[1,2]. A difficulty was observed in applying this method to urine in which the œstrogen titre was low, for example, to non-pregnancy urines, since the values obtained with the fluorometric method for normal male and female urines were higher than those yielded by the bioassay (Allen–Doisy test). In addition, a 'quench ing' effect has been observed. These findings suggested that another substance or substances were augmenting the fluorescence produced by the œstrogens. The 'non-specific fluorescence' has also been observed by Engel[3,4], who prepared his urinary extracts by the countercurrent partition method.

Another difficulty lay in the comparatively low recoveries of the œstriol added to urine[2].

It was therefore desirable to revise the partition procedure in order so far as possible to eliminate the 'non-specific fluorescence', and also to improve the recovery of the added œstrogen.

Substitution of ether for benzene in the initial extraction of the œstrogens from the urine led to improved recovery of œstriol. This step merely constituted a return to the original method of B. Zondek[5], who used ether for extracting the œstrogenic substances from urine. Recently, Engel also recommended the use of ether instead of benzene[3,4]. On extraction of the ether solution with N sodium hydroxide, the œstrogens (œstradiol, œstrone and œstriol) passed almost quantitatively into the alkaline phase, after which adjustment to a pH of *c.* 8 was again extracted with ether and then evaporated to dryness. For the partition of the three urinary œstrogens into œstrone–œstradiol and œstriol fractions, many pairs of solvents were tried. The most suitable partition was obtained between benzene/petroleum ether (1 : 1) and water, in which œstradiol and œstrone remained n the organic phase, whereas œstriol passed into the water. From this point the two fractions were treated separately.

The benzene / petroleum ether (œstrone–œstradiol fraction) was evaporated to dryness, the residue was taken up in ether, which was evaporated after washing with 30 per cent sulphuric acid, saturated sodium bicarbonate and water. The residue was dissolved in an accurately measured amount of ethanol, from which aliquots were taken for fluorometry.

The œstriol fraction was treated as follows. The aqueous layer, adjusted to pH 8 (according to Engel[3,4] much less fluorogenic material is extracted at this pH), was extracted with ether. The ether solution was washed with saturated sodium bicarbonate and water, and evaporated. The residue was dissolved in 50 per cent methanol, which was washed with carbon tetrachloride and evaporated to dryness. The residue was redissolved in an accurately measured quantity of ethanol, and aliquots of this solution were used for fluorometry.

The development of the fluorescence was essentially he same as that described previously[1,2]. The readings of the fluorescence in the present study were carried out with the aid of a Farrand fluorometer instead of the Coleman fluorometer previously employed. The primary light was filtered with a Farrand interference filter with the transmission at 440 mμ. The secondary filter (to the photomultiplier) was a Farrand interference filter with the transmission at 530 mμ. For eliminating any non-specific fluorescence he readings were repeated using a Corning 5860 filter which passes the 365 mμ mercury line instead of the 440 mμ filter. Subtracting the second reading from the first yielded linear responses for œstradiol, œstrone and œstriol in pure solutions, and it can be used to advantage in urinary extracts. Recoveries obtained using this method have been of the order f 85 ± 15 per cent. The non-specific fluorescence was greatly reduced, and as little as 20 γ œstrone nd about 30 γ œstriol per litre could thus be determined.

A detailed account will be published elsewhere.

I am grateful to Prof. Bernhard Zondek for his interest in, and support of, this investigation. I am also much indebted to Miss L. Berlin, Mr. A. Schwager and Mrs. L. Beyth for their valuable assistance. The investigation has been aided by a grant from the Jane Coffin Childs Memorial Fund for Medical Research.

Determination and Occurrence of Fluorescent Substances in the Neutral Fraction of Urinary Extracts

IT has been shown that the natural phenolic œstrogens produce fluorescence on being heated with phosphoric acid[1,2]. When applying this method to urinary extracts, it was found that a non-specific fluorescence obscures the readings for the œstrogens, especially in the 'strong phenolic fraction'—the œstriol fraction. On attempting to purify the œstrogenic fractions of the non-specific fluorescence, we observed that a great part of it was non-phenolic, but was due to a 'neutral' substance or substances, which were carried over in the partition procedure then used (a modified Bachmann–Pettit method[3]) to the œstrogenic fraction.

A new procedure was therefore elaborated for the œstrogens (see the preceding communication) and the neutral fraction was studied concurrently. Briefly, the procedure for the preparation of the neutral fraction was as follows. The hydrolysed urine was extracted with ether, and after washing with N sodium hydroxide, saturated sodium bicarbonate and water, it was evaporated to dryness. The residue was dissolved in a small amount of ethanol. Benzene/petroleum ether (1 : 1) was added and the mixture was transferred to a separating funnel. It was vigorously extracted with distilled water, and the aqueous phase was in turn extracted with ether, which after washing with saturated sodium bicarbonate and water was evaporated. The residue was dissolved in 50 per cent methanol, which was then washed with carbon tetrachloride. The methanol was distilled off *in vacuo*, and the residue redissolved in ethanol, from which samples were taken for the development of the fluorescence with phosphoric acid in the usual manner[1,2]. For determination of the fluorescence a Farrand fluorometer was used, and the technique was similar to that described in the preceding communication.

Details about the fluorescent substance or substances in the neutral fraction will be reported elsewhere.

Here we would like to mention that these substances seem to be of biological importance if judged by the fact that they have been found in small amounts in every human urine examined. Their excretion seems to be somewhat increased at the time of ovulation; a considerably increased excretion has been found so far (*a*) in cases with adrenogenital syndrome (pseudo-hermaphroditism), (*b*) in arrhenoblastoma, (*c*) in the last months of pregnancy. Excretion increased following injection of 300 mgm. of adrenotropic hormone over a period of three days.

The chemical constitution of the fluorescent substance or substances of the neutral fraction—probably of adrenal cortical origin—are being studied in collaboration with Prof. T. Reichstein of Basle.

We are much indebted to Miss L. Berlin, Mr. A. Schwager and Mrs. L. Beyth for their assistance. This investigation has been aided by a grant from the Jane Coffin Childs Memorial Fund for Medical Research.

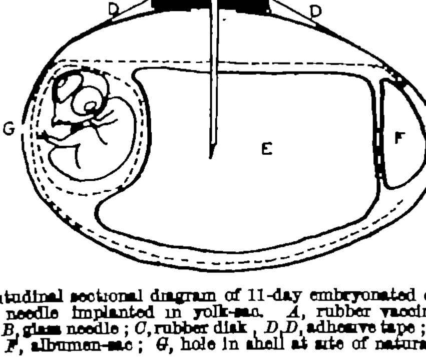
A Method for Administering Chemotherapeutic Agents to Chick Embryos

THE technique described was developed for the purpose of studying the action of chemotherapeutic agents, given in divided doses by the yolk-sac route, on the proliferation of vaccinia virus in embryonated eggs.

A glass needle is prepared by drawing out a piece of tubing of approximately 6 mm. internal diameter to a capillary 4·0–4·5 cm. long. The wide end of the tube is cut off 1·0 cm. from the point of narrowing, and the capillary end is bevelled to a sharp point on the flat surface of a rotating 'Carborundum' dental disk. (It is advisable to wear an eye-shield during this operation.) The wide end of the needle is closed with a small rubber vaccine-bottle cap. A number of these assemblies are prepared and autoclaved.

11-Day embryonated eggs are candled, and a point marked in the centre of the long axis where the chorio-allantois is well developed, but as far from the embryo as possible. A triangle of shell is cut away from this point, the shell membrane is pierced, and the chorio-allantoic membrane is 'dropped' by suction through a hole drilled into the natural air-sac. The yolk-sac can then be seen lying directly beneath the opening.



Longitudinal sectional diagram of 11-day embryonated egg with glass needle implanted in yolk-sac. *A*, rubber vaccine-bottle cap ; *B*, glass needle ; *C*, rubber disk ; *D*,*D*, adhesive tape ; *E*, yolk-sac ; *F*, albumen-sac ; *G*, hole in shell at site of natural air-sac

The glass needle, which has been forced for about 3 cm. of its length through the centre of a sterile rubber disk of the type used in 1-oz. 'Universal Container' caps (2·75 cm. in diameter), is next inserted through the chorio-allantoic membrane, and into the yolk-sac, until the rubber disk rests upon the shell, to which it is then secured with strips of adhesive tape (see diagram). One worker, with an assistant to drill the eggs, can set up thirty to forty such preparations within an hour.

The chorio-allantois can be infected with the test virus before insertion of the glass needle, or afterwards by injection with a fine hypodermic needle through the rubber disk.

Injections of the chemotherapeutic agent can now be made at desired intervals through the vaccine cap with a hypodermic syringe. The small quantity of fluid remaining in the glass needle after injection is expelled into the yolk-sac by the further injection of a small quantity of air. Up to 1·0 ml. of fluid may be thus administered in divided doses.

At the end of the experiment, the glass needle is withdrawn, the rubber disk removed, and the egg opened for examination. The interference with the chorio-allantois is minimal. A small hole surrounded by a very small area of tissue reaction will be seen where the needle has passed through. The embryos tolerate this procedure remarkably well; in our hands deaths attributable to inoculation trauma have amounted to less than 5 per cent of the total treated, in experiments lasting 48–72 hr.

The advantages claimed for this method are: (*a*) the chemotherapeutic agent is not given by the same route as the virus, thus obviating any direct virucidal action; (*b*) repeated injections may be given under completely sterile conditions, maintaining a high concentration of test agent in the tissues; (*c*) the injections are placed in the yolk-sac with absolute precision, especially in older embryos in which the usual injection route via the air-sac is not always satisfactory; (*d*) repeated doses may be given to large numbers of embryos with rapidity.

Isolation of 2 : 3 : 4 : 6-Tetramethylpyridine from Coal Tar

DURING an investigation, previously referred to[1] of the nitrogenous bases extracted by sulphuric acid from the 'benzol absorbing oil' fraction of vertical retort coal tar, a tertiary base has been isolated which has been proved to be 2 : 3 : 4 : 6-tetramethylpyridine, a compound which has not hitherto been reported as a constituent of coal tar. This compound however, has been previously isolated from Fushun shale oil by Eguchi[2], and from Scottish shale oil by Benzie and Milne[3].

The base was isolated from a fraction (boiling point 135–135·2° C./100 mm.) obtained by high-efficiency fractional distillation (efficiency approximately 100 theoretical plates) as follows. The fraction was treated with the theoretical amount of picric acid in three equal portions, the picric acid being added as a saturated alcoholic solution. In this way three batches of picrate were obtained, the first two of which melted at 110–120° C. and consisted of fine needles. The third batch of picrate melted at 150–170° C.

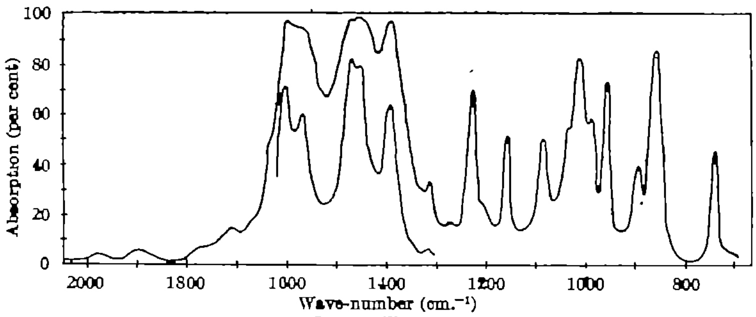
The first two fractions of picrate were combined and recrystallized repeatedly from 95 per cent alcohol until a constant melting point of 122–123° C. was attained. This material was then recrystallized twice from acetone, thereby raising the melting point to 122·5–123° C. This melting point agrees very well with the value of 122·5–123·5° C. given by Benzie and Milne for 2 : 3 : 4 : 6-tetramethylpyridine picrate, and a mixed melting point determination showed no lowering.

The free base was regenerated from this pure picrate by treatment with caustic soda and steam distillation. It was then dried and redistilled. The pure base was found to be a colourless liquid with quite a pleasant smell and the following physical characteristics.

b.p. 203° C./750 mm. Lit. 203·3° C./760 mm. (ref. 2)
n_D^{25} 1·5087 Lit. 1·5084 (ref. 2)
D_4^{25} 0·9322 Lit. 0·9345 (ref. 3)

From this pure product, the picrolonate (m.p. 225·5° C., decomp.) and the methiodide (m.p. 192–193° C.) were prepared. The value found for the picrolonate was identical with that given by Benzie and Milne, and a mixed melting point determination showed no lowering.

The infra-red absorption spectrogram of the base, which was recorded by Mr. J. L. Hales of the Department of Scientific and Industrial Research, was found to be identical with that for the compound obtained by Benzie and Milne and to follow the graph reproduced herewith.



50-μ capillary cell

The above evidence of infra-red absorption spectrograms, physical properties, melting points and mixed melting points, is sufficient to prove that this base, isolated from coal tar, is 2 : 3 : 4 : 6-tetramethylpyridine.

The isolation of this compound leaves only two of the nineteen possible methyl homologues of pyridine still unidentified in coal tar. These are 3 : 4 : 5-trimethylpyridine and pentamethyl pyridine, neither of which has been reported as being isolated from any natural source, nor has either been prepared.

A complete account of this work will be published at a later date.

Paper Chromatography of Flax Fibre Polyuronide Hemicellulose

IT is well known that pectic substances are broken down during the retting of flax. There is evidence that other polyuronides also occur in flax straw and are attacked in retting[1]. Their constitution is therefore of great interest in flax research. The sugar constituents of the polyuronide hemicellulose have been investigated. This substance was obtained from fibre separated from flax straw by purely mechanical means without previous retting. Finely ground fibre was extracted successively with ether, petroleum ether, ethanol and water. Pectic substances were removed with seven 30-min. extractions with boiling 0·5 per cent ammonium oxalate solution. The residue, after washing with water, ethanol and ether followed by air-drying, was extracted twice for 24 hr. with cold 4 per cent sodium hydroxide solution. The filtered extract was acidified with glacial acetic acid and the hemicellulose was precipitated with ethanol. The precipitate was well washed and dried from ethanol and ether. Approximately 3 gm. of polyuronide hemicellulose was obtained as a slightly greyish powder, lignin content 1·8 per cent, uronic acid anhydride content 7·1 per cent (19 per cent hydrochloric acid method[2]).

The hemicellulose was hydrolysed with *N* sulphuric acid at 100° C. for six hours. After cooling, solid barium carbonate was added until the liquor was no longer acid to congo red paper. The clear liquor obtained after centrifuging was evaporated on a hot water-bath and the residue dissolved in pyridine[3]. Mineral matter was separated by centrifuging, the solution was allowed to evaporate in a stream of air and a thin syrup was prepared for paper chromatography.

The procedure of Jermyn and Isherwood[4] was followed and the following solvent mixtures were used: (*a*) butanol – ethanol – water (4 : 1 : 5)[5] and (*b*) (4 : 1·1 : 1·9)[6] parts by volume; (*c*) butanol – acetic acid – water (2 : 1 : 1)[6] and (*d*) ethyl acetate – acetic acid – water (3 : 1 : 3)[4]. Known sugar solutions (1 per cent w/v) were run simultaneously on the filter paper with the hemicellulose hydrolysate for identification purposes. The positions of the sugars were revealed by brushing with aniline hydrogen phthalate[7] or *p*-anisidine hydrochloride[8]. Solvents (*a*) and (*b*) did not separate arabinose and mannose, but (*c*) and (*d*) showed the presence of both in the hydrolysate. All four solvents showed the presence of galactose, glucose, xylose and rhamnose. No ketoses were detected. In addition to these six sugars, when a more concentrated syrup was used, two faint spots were observed of R_D values (distance moved relative to rhamnose or *iso*-dulcite)[6] in solvent (*c*) 0·84 and 0·92 respectively.

Flax fibre polyuronide hemicellulose therefore contains arabinose, xylose, galactose, glucose, mannose and rhamnose, together with a uronic acid constituent, the nature of which is under investigation, and traces of two other substances. The flax plant is seen to contain a variety of polyuronides, namely, pectic substances, hemicellulose, seed mucilage and probably polyuronides of a gummy nature. An intensive study of this one species may therefore throw some light on the origin of these carbohydrates.

This communication is published by permission of the Home Flax Production Department, Board of Trade.

Quantitative Chromatographic Separation and Estimation of Cadmium in Copper Alloys using Paper Strips

Bishop and Liebmann[1] have described the quantitative separation of zinc from soldering alloys by chromatography on cellulose columns followed by polarographic estimation. We employ a similar method for the determination of small amounts of cadmium in copper–cadmium alloys, except that we use paper strips of normal thickness.

Our procedure is briefly as follows. A solution of a weighed amount of the alloy is prepared in the minimum volume of nitric acid diluted 1 to 3, and made up accurately in a volumetric flask to a cadmium concentration in the range 10^{-4} to 10^{-3} gm. per millilitre; 0·3 ml. of this solution is placed by means of an 'Agla' micrometer syringe (Burroughs Wellcome, Ltd.), 5 cm. from one end of a 4 cm. × 45 cm. strip of Whatman No. 1 paper. Spreading of the band of solution may be lessened by applying the solution in 0·1 ml. or smaller portions and allowing each to dry before applying the next. The chromatogram is developed by a method very similar to that described by Linstead *et al.*[2], but using methyl ethyl ketone plus 30 per cent by volume of A.R. hydrochloric acid as the developing solution. After about sixteen hours the chromatogram is allowed to dry in air. The copper band, which is yellowish-green in colour, begins about 20 cm. from the starting position; the cadmium band commences within a few millimetres of the front of the copper band and extends for 2–4 cm. It is usually accompanied by a brown to pink coloration apparently derived from the developing solution; a freshly mixed solution gives less of this coloration than an old one. No interference with the separation has been observed, but the front of the copper band is more easily visible when the coloration is absent.

The whole of the lower portion of the strip containing the cadmium is extracted and washed with boiling 1 per cent hydrochloric acid. The filtrate and washings are combined and evaporated gently to dryness. The residue is treated with about 0·5 ml. of 60 per cent perchloric acid and again evaporated to dryness to destroy traces of organic matter which have been found to interfere sometimes with the polarographic wave-form. The residue is then dissolved in exactly 2 ml. of 0·5 *M* potassium chloride solution in 1 per cent hydrochloric acid and a portion polarographed in a 2-ml. cell after passing hydrogen for five minutes. As an internal standard, 0·002 ml. of a standard solution of cadmium metal in A.R. hydrochloric acid is then introduced directly into the polarographic cell with the 'Agla' syringe.

For alloys containing 0·2–1·3 per cent cadmium, the coefficient of variation of our results has been found to be of the order of 1 per cent, which compares very favourably with the spectrographic solution – spark method, which we have found to give a coefficient of variation of about 3 per cent. The method is less time-consuming and much more convenient than the usual macro-chemical methods, and it is suggested that it could be readily adapted for other analyses.

It is hoped to describe the method in greater detail elsewhere.

A large part of the credit for this work must be accorded to Miss J. Houghton, who has carried out the practical work, and without whose patience and practical suggestions its completion would have been long delayed. Thanks are due to Dr. L. G. Brazier, director of research and engineering, British Insulated Callender's Cables, Ltd., for permission to publish this communication.

Carbohydrate Primers for Q-Enzyme

For some time we have been engaged in a study of the starch-synthesizing enzymes of *Polytomella caeca*, a flagellate which produces starch from sodium acetate and ethyl alcohol, but not from sugars[1]. This starch is similar to most natural starches inasmuch as it consists of amylose and amylopectin components, the latter being the major constituent[2]. It has already been reported by Lwoff, Ionesco and Gutmann[1-3] that *Polytomella caeca* contains a phosphorylase which utilizes glucose-1-phosphate as the substrate for the synthesis of an iodophilic polysaccharide; this claim has been verified in these laboratories[4]. However, since phosphorylases are known to catalyse the formation of only 1 : 4-α-glycosidic linkages, it seemed probable that, for the synthesis of the branch points of amylopectin, the organism must employ a second enzyme, similar to the *Q*-enzyme of the potato[5] or the 'branching factor' of liver and heart[6].

This second enzyme has now been isolated[4] by a method which was essentially that used by Barker, Bourne and Peat[7] in the case of potato *Q*-enzyme. The protozoal enzyme converts amylose into a polysaccharide, which is stained red with iodine and has been proved to belong to the amylopectin–glycogen class[4].

The purpose of the present communication is to record certain phenomena encountered during the early stages of the reaction catalysed by the *Q*-enzyme of *Polytomella caeca*; these phenomena have not been described in reports of the properties of *Q*-enzyme samples derived from other sources. When dilute solutions of the protozoal enzyme were incubated with amylose samples containing different degrees of amylopectin impurity, the rates of reaction, as measured by the changes in the iodine-staining powers of the digests, were markedly different; in general, the higher the blue value[9] of the amylose the slower was the reaction-rate. Indeed, with amyloses having the highest blue value there was an appreciable time-lag in the initiation of the reaction and, thereafter, the rate of reaction increased progressively. The lag phase was reduced considerably and the subsequent reaction-rate increased by the introduction of potato amylopectin, the native amylopectin of *Polytomella caeca*, glycogen, dextrins, or commercial maltose, whereas inulin, xylan, dextran, cellobiose, lactose, sucrose, glucose, galactose or fructose did not show this effect. Thus it would seem that, for the display of optimum activity, samples of the *Q*-enzyme of *Polytomella caeca* require the presence of a carbohydrate primer containing glucose units mutually linked by 1 : 4-bonds in the α-configuration. The autocatalytic reaction observed with the purest amyloses in the absence of added primer may be attributed to the ability of the products of the reaction to function as primers.

That the observed effects were not due to the activation of possible traces of amylase impurities in the enzyme samples was shown by the fact that the small reducing powers developed during the course of the enzyme action were not influenced by the presence or absence of primer. Pending further work on this problem, we tentatively suggest that it is the *Q*-enzyme itself which requires the carbohydrate primer. If this be true, then the phenomenon is analogous to that obtaining in the phosphorylase-catalysed synthesis of linear chains, for it is already generally agreed that a 1 : 4-α-linked glucose polymer is required to initiate the synthesis of amylose from glucose-1-phosphate[9].

We are indebted to Prof. M. Stacey for his interest in this work, and to the Royal Society and the Department of Scientific and Industrial Research for grants to two of us (S. A. B. and A. B.).

Pregnan-7-ol and Pregnan-12-ol

Ruff and Reichstein[1] have described a pregnan-7-ol and a pregnan-12-ol prepared by Wolff–Kishner reduction of acetoxypregnane ketones. They state that these two substances are probably the 7α- and 12α-hydroxy compounds; but since epimerization during Wolff–Kishner reduction is not excluded, they name them provisionally '7ξ' and '12ξ'[2]. The molecular rotations of pregnan-7ξ-ol and of pregnan-12ξ-ol and their derivatives show that the two new compounds are indeed 7α and 12α.

Barton and Klyne[3] have summarized the molecular rotation contributions of a large number of substituents in the steroids. The terms ΔO and ΔA have been used for the contributions of hydroxyl and acetoxyl groups, and Δ_1 (Barton[4]) for the molecular rotation difference on acetylation ($\Delta A - \Delta O$). The ΔO, ΔA and Δ_1 values for pregnan-7ξ-ol and -12ξ-ol are compared with the standard values in the accompanying table.

Molecular rotation difference	Compound	Δ Values for ξ compounds[1]	Standard Δ values[3] α	β
ΔO	Pregnan-7-ol	− 54	− 79	+95
ΔO	,, -12-ol	+ 43	+ 93	+50
ΔA	,, -12-ol acetate	+205	+280	+76
Δ_1	,, ,,	+162	+187	+26

The ΔO value for pregnan-7ξ-ol shows that it must have the 7α configuration. While no conclusions can be drawn from the ΔO value of pregnan-12ξ-ol, the ΔA and Δ_1 values for its acetate prove clearly that it must have the 12α configuration.

Use of Nuclear Research Emulsions for Fast-Neutron Dosimetry

THE use of nuclear research emulsion for the measurement of fast neutron doses has been described by Titterton[1]. The purpose of this communication is to describe an extension of this technique to the measurement of energy absorption in hydrogenous material irradiated by fast neutrons.

A unit of biological significance in irradiation of living material is the energy absorption of the material from primary or secondary ionizing particles. It has been shown theoretically by Mitchell[2] that in tissue irradiated by fast neutrons of energies between 0·5 and 5 MeV., 90 per cent of the energy deposition is due to elastically scattered protons. Such recoil protons may be observed and their ranges measured in nuclear research emulsions exposed to fast neutrons. On the assumption that the ratio of the energy deposition per unit volume of emulsion and tissue is equal to the ratio of the atomic density of hydrogen in the two materials, the energy deposition in tissue can thus be determined.

Ilford *C*.2 plates of 400 microns nominal thickness were exposed to a beam of D + D neutrons from the electrostatic generator at the Radiotherapeutic Research Unit, Hammersmith; the maximum spectral energy of the neutrons was 5 MeV. The energy deposition in a volume of emulsion defined by a rectangular parallelepiped was determined by measurement of the ranges of all proton tracks observed in the volume, using the range–energy relation for that emulsion[3] for determination of the corresponding energies. Boundary effects were taken into account by scanning a volume of emulsion which was surrounded in every direction by a thickness of emulsion greater than the maximum proton range. This was effected by scanning between two planes parallel to the free surface of the emulsion at 100 microns distance from the top and lower surfaces of the emulsion respectively.

Tracks totally enclosed in the parallelepiped were measured, also the partial lengths within the scanned volume of those tracks which crossed the horizontal boundaries. To enable the energy dissipation of a proton which starts in the scanned volume and proceeds out of it to be determined, it is necessary to measure both the full and enclosed length of its track. The energy dissipation in the enclosed portion of the track is then obtained by subtracting the energy dissipation in the residual portion of the track from that of the whole track.

Since in this energy region the neutron–proton scattering is isotropic in centre-of-gravity co-ordinates, recoil protons of all energies from zero to the incident neutron energy are emitted with equal probability. Tracks produced by low-energy protons are difficult to detect and measure, more especially if they have a large angle of dip. The energy deposition by protons of energy less than an arbitrary value E_1 may, however, be applied as a correction to the total energy deposition measured. The value of this correction factor is small, and for mono-energetic neutrons of energy E_0 is $E_0^2/(E_0^2 - E_1^2)$. For *C* 2 emulsion and a minimum track-length of four microns, corresponding to $E_1 = 0{\cdot}40$ MeV., the correction is less than 5 per cent when E_0 is greater than 2 MeV.

The correction for a complex neutron spectrum can be calculated if the energy distribution of the neutrons is known.

In a typical plate, the scanning of 250 fields of view gave 851 complete tracks of energy greater than 0·4 MeV., and 41 partial tracks in a volume corresponding to 0·493 mm.^{3} of unprocessed emulsion. The total energy dissipation in this volume was found to be $1{\cdot}37 \times 10^3$ MeV. The energy spectrum of the neutrons was determined from an Ilford *C*.2 plate of 200 microns thickness which was simultaneously exposed in the same position as the 400-micron plate, the analysis being made by the standard method of measurement of the ranges of forward-scattered protons[4]. From this spectrum the correction factor for protons of energy less than 0·40 MeV. was found to be 4 per cent. Hence the total energy dissipation is found to be 4·60 ergs per c.c. of emulsion. Assuming the tissue to have unit density and 11 per cent hydrogen content by weight, and the *C*.2 emulsion to have a normal hydrogen content of 0·056 gm./c.c.[1], the equivalent tissue dose is calculated to be 9·04 ergs/gm. or 0·11 rep.

Experiments indicate the suitability of this method for determination of the energy deposition due to a fast-neutron dose up to 0·2 rep.; larger doses lead to an inconveniently high track density for microscopic observation. Further experiments are in progress, in conjunction with Dr. L. H. Gray, to compare the results obtained by this method and the ionization chamber[5].

I am indebted to the Medical Research Council for permission to expose plates at the Radiotherapeutic Research Unit, Hammersmith, the British Empire Cancer Campaign for the award of a research fellowship, and Prof. J. Rotblat for his interest and encouragement throughout the work.

A New Calculation of the Cohesive Energy of Metallic Beryllium

Following the success of the Wigner–Seitz cellular method[1] for the calculation of binding energies of the alkali metals, a treatment for divalent metals was given by Herring and Hill[2], who carried out detailed calculations for beryllium, taking into account the effect of the Brillouin zone boundaries. Recently, a simpler method has been used by Raimes[3] for magnesium, and reasonable agreement with experiment was obtained. This communication presents the results of a new calculation for beryllium, similar to that of Raimes, undertaken with the object of ascertaining whether a simpler treatment could be applied to beryllium, and whether Raimes's suggestion regarding the correlation energy in the free atom would be satisfactory in this case.

Wave functions corresponding to the lowest state of an electron in the lattice have been obtained by numerical integration for eight values of the radius r_s of the atomic sphere. The field acting on a given electron was taken to be that of the ion-core[4] plus that due to all the electrons with opposite spin. The eigenvalue of the Schrödinger equation was found by approximating successively until the boundary condition was satisfied at $r = r_s$ (gradient of wave function equal to zero). The Fermi energy was obtained in the form α multiplied by free electron value, and the effective mass parameter α was determined by Bardeen's method[5]. Values of α were obtained by numerical integration for all eight values of r_s; at the experimental radius $r_s = 2{\cdot}37$ Bohr units, the value $\alpha = 0{\cdot}616$ was obtained, in exact agreement with Herring and Hill, but the present calculation gives somewhat higher values for larger values of r_s. The free electron expressions for the exchange and correlation energies have been used, as in Raimes's paper. Exchange interaction between valence and core electrons was neglected in the metal and in the free atom; moreover, interaction between the ion-cores was assumed to be negligible.

For the free atom the energy of the valence electrons was taken from the Hartree approximation[4]; in the treatment of Herring and Hill the experimental value was used, which resulted in a low value for the cohesive energy. The correlation energy was derived according to Raimes's suggestion of a proportion of the total energy of the valence electrons or of the Coulomb interaction energy. For beryllium both methods give the same result, namely, − 0·013 Rydbergs/electron.

Finally, the work function was evaluated according to the method described by Herring and Nichols[6], using the calculated total energy (− 1·086 Rydbergs/electron) at the calculated lattice constant ($r_s = 2{\cdot}34$

	Present calculation	Herring and Hill	Experimental
Lattice constant (Bohr units)	2·34	2·23 to 2·57	2·37
Cohesive energy (kcal./mole)	84	53	75
Compressibility (cm.^{2}/kgm. × 10^7)	8·0	7·5 to 11·3	7·8
Work function (volts)	−0·3	−1·9	3·9

Bohr units). The complete results are shown in the table and, with the exception of the work function, show very satisfactory agreement with experiment.

The experimental compressibility is taken from Bridgman[7] and refers to 30° C.; the calculated values refer to absolute zero.

A detailed account of these calculations will be published elsewhere.

Mechanical Properties and Structure of Sol-type and Gel-type Gelatine Films

FILMS can be prepared from aqueous sols of gelatine either by evaporating off the water slowly at room temperature, when gel formation precedes dehydration, or directly from the sol by maintaining the drying temperature at a sufficiently high level (for example, 60° C.), which defers the development of structure until the drying process is nearing completion. Pinoir and Pouradier[1] showed that thin sol-type films produced in this way were soluble in water at room temperature, whereas the gel-type films merely swelled under the same conditions. They pointed out the significance of their observation in view of the earlier discovery of Katz and his colleagues hat gelatine film prepared at room temperature gave a crystalline X-ray powder diagram, whereas that given by the film prepared hot was of the more amorphous type. They inferred that the difference in solubility between the two was caused by the more extensive organization and bonding of chains in the gel type.

We have produced gel-type and sol-type films by regulating the temperature of drying as described bove, and have made an X-ray examination of heir structure. In general conformity with Katz's findings, the results suggest the presence of small randomly arranged crystallites in the sol-type film, and of much larger crystallites in the gel type. The crystallites in the gel type tend to lie in the plane of he film, but are randomly arranged within this plane. This orientation in a direction parallel to the plane of the film has been found in films made from other ubstances in which development of a network ructure precedes drying out. The orientation is no oubt caused by the uni-directional collapse of the etwork as the film contracts on drying in a direction erpendicular to the supporting base.

When immersed in boiling methanol, the gel-type film contracted very considerably in length and width and increased in thickness; the sol-type film softened with the same treatment but its dimensions did not change. This thermal contraction of the gel-type film indicates that the chains in the original film were in the (at least) partially extended condition in the plane of the film, and the lack of it in the sol type that the chains were fully, or almost fully, contracted in this film. It seems likely, therefore, that, starting with a state of contracted chains in the sol, straightening of the chain results as a necessary consequence of its association into an ordered crystalline structure, and the degree of straightening should depend on the length of the crystallite. In the preparation of the sol-type film, the rapidity with which the structure is developed in the crowded system of contracted chains favours the development of many small crystallites, while the more leisurely development of structure in the more widely spaced chain system in the gel and in the subsequent slow drying is consistent with the presence of much more extensive crystallites in the gel-type film.

The tensile properties of the two types of film have been measured after conditioning in atmospheres of relative humidity ranging from 45 to 85 per cent, and the results of these tests (see table) are consistent with the structural picture outlined above.

TEMPERATURE OF PREPARATION OF FILM AND THE AMBIENT HUMIDITY DURING TESTING: EFFECTS ON TENSILE PROPERTIES

Temp. of preparation of film (° C.)	Relat. hum. during testing (per cent)	Tensile properties Tensile strength (kgm./sq. cm.) Mean	 S.D.	 Extension at break (per cent) Mean	 S.D.
20°	45	910	48	1·9	0·2
60°	45	654	31	1·1	0·1
20°	55	832	52	2·2	0·3
60°	55	585	33	1·5	0·1
20°	65	646	59	3·7	0·7
60°	65	350	22	1·7	0·2
20°	75	418	29	10·2	1·7
60°	75	172	36	46·1	5·6
20°	85	170	38	23·8	3·6
60°	85	81	11	179	20

S.D. = standard deviation.

As would be expected, the structure containing the larger crystallites (gel type) is always stronger than that in which the inter-chain bonding is less extensive. For both types of film the tensile strength falls, and the extension at break increases, with increasing ambient relative humidity, and is a consequence of the progressive weakening of the inter- and intra-chain bonds by the increasing amount of water absorbed. Up to 65 per cent relative humidity, the extension is small and is probably mainly due to a partial failure of these bonds since, although small, it does increase appreciably with the relative humidity. At relative humidities of 75 and 85 per cent, the extension at break is much greater than before, and is much greater in the sol type than in the gel type. It is evident that failure of the inter- and intra-chain bonding is much more nearly complete at these humidities, so that the chains themselves are able to extend. When this occurs, the contracted chains in the sol-type film are able to allow a much greater extension than the comparatively extended chains in the gel type. Even after extending to the point of breakage, the films recover their original length (to within 5 per cent) on relaxing the stress, and it seems likely that the elastic behaviour could be largely accounted for in terms of the entropy change on extension.

We hope to publish these results in more detail elsewhere at a later date.

Magnetic Properties, Internal Strains, and the Bauschinger Effect in Metals

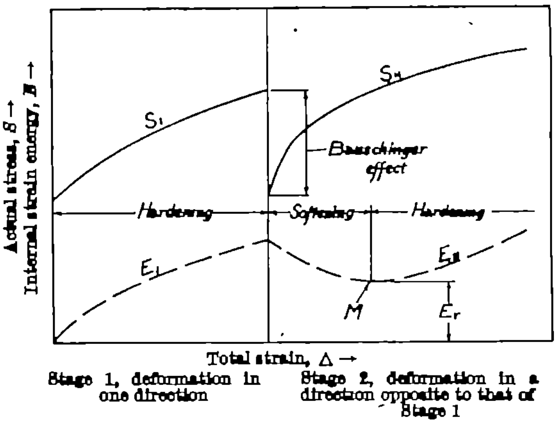
Wilson[1] has recently reported that the intensity of magnetization of a high-carbon steel increases with plastic deformation of one kind, but that it suffers a recession after a relatively small additional plastic strain applied in a direction opposite to that originally used. I suggest that these results could be predicted from an analysis of the Bauschinger effect.

The conventional explanation of this effect[2] accounts for the abrupt fall of resistance to deformation when the direction of the external stress is reversed (see diagram, S-curves). It is easy to see, however, that the simultaneous decrease of internal strain energy E of the cold-worked metal can be only gradual, and that E must reach a minimum M before starting to rise again. Since work-hardening is never fully reversible, some residual strain energy E_r remains latent in the metal.

This analysis implies that all energy-dependent properties affected in one manner during unidirectional deformation must be affected in the opposite manner on subsequent reversed straining. In fact, tensile elongation, recrystallization temperature, and sharpness of X-ray diffraction rings and spots, do behave in the way expected[3], and in a detailed report[4] it will be shown that the Bauschinger effect is also accompanied by appreciable mechanical softening. The maximum decrease of Vickers hardness was 3–10 points in steels with 0·07–0·14 per cent carbon, and up to 26 points in medium- and high-carbon steels with 0·45–1·15 per cent carbon. Equivalent results were obtained with non-ferrous metals, and the amount of softening was consistent with the magnitude of the Bauschinger effect in each case.

Upon these findings, a general rule was formulated stating that work softening occurs whenever the method of cold working used tends to produce an internal stress system different from that left after the preceding treatment, irrespective of whether the latter was of mechanical or of thermal nature. Since the building-up of a new system of internal stresses must be preceded by a partial destruction of that existing previously, there is a transient decrease of E, demonstrated by softening.

The above rule immediately explains why the hardness of sorbitic and troostitic steels either remains constant[5,6] or even falls substantially[6,7] during the early stages of cold working. The same apparently applies to magnetic properties[1], and probably to density as well. Obviously, if 'back straining' is continued, the intensity of magnetization will also ultimately increase, but only after passing through a minimum, just like E in the right-hand side of the diagram.



Actual stress, S →

Eᵣ
Total strain, Δ →
Stage 1, deformation in one direction
Stage 2, deformation in a direction opposite to that of Stage 1

Diagrammatic representation of changes of resistance to deformation S, and of internal strain energy E, associated with the Bauschinger effect. It is assumed that for $\Delta = 0$, also $E = 0$

It seems, therefore, that Brinell or Vickers hardness tests provide a more convenient and sound basis for investigating internal stresses in metals than magnetic tests. Not only are they less cumbersome, but also they are more sensitive, since for reversed deformations varying from 4 to 8 per cent no difference whatever in intensity values was detected (ref. 1, curve 3). Furthermore, hardness tests are equally applicable to steels and non-ferrous metals, and are also sensitive to directional variations of properties. Finally, although the relations between hardness and stress values are not always clear, they are certainly simpler than those between magnetic properties and mechanical stresses.

Large Prime Numbers

For about seventy-five years the largest known prime number has been $P = 2^{127} - 1$, identified as such by Edouard Lucas. It has remained the largest known in spite of many attempts to identify larger ones, although there have been conjectures and claims insufficiently substantiated or entirely unproved.

Recently we have prepared a routine for testing on the Edsac the primality of numbers of the form $kP + 1$, with P as defined above, and have found ten values of k that give prime numbers. The largest of these gives the present (June 7) largest known prime, namely,

$$934(2^{127} - 1) + 1.$$

J. C. P. Miller
June 7. D. J. Wheeler

Note added in proof (*October* 8). Further work on the Edsac by Wheeler and myself has demonstrated the primality of

$$978(2^{127} - 1) + 1$$

and culminated in early July in the identification of the present largest known prime,

$$180(2^{127} - 1)^2 + 1.$$

Also, in early July, A. Ferrier, of France, using a desk machine, demonstrated the primality of

$$(2^{148} + 1)/17,$$

which is the second largest known prime.

Saturday, November 17

British Psychological Society, Social Psychology Section (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Prof. R. W. Russell: "Psychological Research in American South-west Indian Cultures"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Analyst in the Department of the Public Analyst—The Registrar and Secretary, The University, Bristol (November 17).

Assistant Lecturer in Applied Mathematics—The Clerk, Birkbeck College, Malet Street, London, W.C.1 (November 17)

Head of the Chemistry Department, Rutherford College of Technology—The Director of Education, City Education Office, Northumberland Road, Newcastle-upon-Tyne 1 (November 17).

Head (Grade II) of the Engineering Department, Chance Technical College—The Chief Education Officer, 215 High Street, Smethwick 41 (November 17).

Lecturer in Agricultural Engineering and Building Construction at Gwebi Agricultural College—The Secretary, Southern Rhodesia Government, 429 Strand, London, W.C.2 (November 24).

Chief Electrical Engineer, an Electrical Engineer, a Water Supply Engineer, and an Industrial Chemist, in the Development Board of the Government of Iraq—J. D. Atkinson, c/o Coode, Vaughan-Lee, Frank and Gwyther, 9 Victoria Street, London, S.W.1 (November 26).

Senior Lecturer in Mechanical Engineering—The Principal, Heriot-Watt College, Edinburgh (November 26).

Weed Ecologist—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (November 28).

Assistant Lecturer in Pathology at the University of Queensland—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (November 30).

Assistant Statisticians in the Civil Service—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting No. 96/51 (November 30).

Chair of Electrical Engineering in the New South Wales University of Technology, Sydney—The Agent-General for New South Wales, 56 Strand, London, W.C.2, or the Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (November 30).

Lecturer in Entomology, and an Assistant in Zoology—The Secretary, The University, Edinburgh (November 30).

Assistant Agricultural Economists (two in the Ministry of Agriculture and Fisheries and one in the Department of Agriculture for Scotland)—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting No. 4097/51 (December 6).

Chair of Psychology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 7).

Senior Principal Production Engineer, Admiralty Production Pool—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4098/51 (December 18).

Senior Lecturer and a Lecturer in Applied Mathematics, and a Lecturer in Pure Mathematics, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (December 15).

Senior Lecturer and a Lecturer in the Departments of Pure and Applied Mathematics, University of Natal, Pietermaritzburg—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 15).

Senior Lecturers and Lecturers in Crop Production, Animal Production, Agricultural Economy, Agricultural Engineering, and Soil Science, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (December 15).

Civil Engineers, Sanitary Engineers and Structural Engineers, in a number of Departments in England and Scotland—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No 3405/A (December 31).

Bacteriologist at the Institute of Medical and Veterinary Science, South Australia—The Agent-General and Trade Commissioner for South Australia, Marble Arch, London, W.1 (Adelaide, January 2).

Professor of Philosophy—The Registrar, University College, Singleton Park, Swansea (January 5).

Aeronautical and Mechanical Engineers (Experimental Officer grade) mainly in the Aerodynamics and Structures Departments at the Royal Aircraft Establishment, South Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W 1, quoting C.572/51A.

Assistant Biochemist (university degree essential)—The Secretary, Preston and Chorley Hospital Management Committee, Royal Infirmary, Preston.

Assistant Educational Psychologist (woman, honours or research degree in psychology and experience in teaching essential) to Child Guidance Clinic and Bristol Schools—Chief Education Officer, Council House, College Green, Bristol 1.

Assistant (Grade B) in the Mechanical Engineering Department—The Principal, Royal Technical College, Salford.

Banana Research Officer (with a university degree in botany, preferably with chemistry, and capable of organizing the work of a small cold storage station), Jamaica—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting 27059/260.

Head of the Mechanical Engineering Department (Grade III), Lecturers in Physics, Chemistry, Mechanical Engineering, Mathematics (Engineering), Production Planning, and Assistants in Biology and allied subjects (Grade B), and English Usage for technical students (Grade A), Wolverhampton and Staffordshire Technical College—The Clerk to the Joint Education Committee, Education Offices, North Street, Wolverhampton.

Horticulturist to take charge of glasshouse and small botanic garden and experimental plot—The Registrar, University College, Singleton Park, Swansea.

Lecturer in the Electrical Engineering Department—The Principal, Northampton Polytechnic, St. John Street, London, E.C.1.

Metallurgists to lead teams engaged on development work involving physical metallurgy, metallography, mechanical working, powder metallurgy, and melting and casting; Metallurgists to undertake development work in one of the fields mentioned above, involving large-scale plant in some cases, Chemical Engineer to undertake large-scale development work on processes for the reduction and recovery of less common metals, at Springfields Factory, Salwick, Preston—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs.

Physical Chemists (Scientific Officer grade) at Ministry of Supply experimental establishments mainly in the vicinity of Waltham Abbey, Sevenoaks and South-East London—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.603/51A.

Physicist or Mechanical Engineer (honours degree in physics or mechanical engineering essential) for research on wire and bar drawing, at Sheffield—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, endorsed 'Wire Drawing'.

Physicists at the Ministry of Supply Radiochemical Centre, Amersham Principal Scientific Officer/Senior Scientific Officer (Ref. A.320/51A) to take charge of the Physics Department, and a Scientific Officer (Ref. A 321/51A) for research and development work related to the production of radioactive isotopes, concerning particularly the absolute calibration of radioactive sources and health physics and associated problems in instrumentation—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, or Almack House, 26-28 King Street, London, S.W.1, quoting the appropriate Ref. No.

Scientific Officers at a Ministry of Supply Design Establishment in Surrey. Physicist (Ref. A.308/51A) preferably with interest in statistics, to plan, supervise and report full-scale field trials which often involve optical and electrical instrumentation; Physicists (Ref. A.307/51A) for general physical investigations and for work connected with fire control equipment, Mechanical Engineer (Ref. C.644/51A) with aptitude for applied mathematics for work on vibration, stress and thermodynamics, or Mechanical Engineer preferably with electrical bias and workshop experience for general mechanical research and development; Electrical Engineers (Ref. D.466/51A) for the application of electrical and electronic techniques to engineering problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

Senior Engineers in the Ministry of Supply to encourage the adoption of improved production processes in the field of aircraft engineering—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.649/51A.

Senior Metallurgist, to take general charge of research on bearing metals, bronze and other alloys containing tin—The Director, Tin Research Institute, Fraser Road, Perivale, Greenford, Middx.

HUMAN RELATIONS IN INDUSTRY

SOME passages in Prof. C. A. Mace's presidential address to Section J (Psychology) at the Edinburgh meeting of the British Association bear so closely on current problems, and notably on that of productivity and industrial relations in industry, that they deserve attention from a much wider audience than that of the psychologists to whom they were originally directed. Prof. Mace remarked, for example, that the collective personality of a group of professional scientific men, the relations within such groups, and the relationship of these groups to other groups in society as a whole, determine the social function of each science as well as the extent of its responsibilities and powers. Moreover, in Great Britain, political and scientific institutions have developed as mutually reinforcing systems, and he suggested that the health and efficiency of any professional body depends in some measure on the quality of the laity it serves. Given the integrity of the particular professional discipline or science, its efficacy depends also on the existence of a critical and educated laity.

The absence of this condition, at least in part, has handicapped progress in productivity and in dealing with problems of human relations in industry; but it is true also in the sphere of science generally that the effective utilization of scientific knowledge depends upon a wider and clearer understanding of what science is and what it is really doing. There is a political if not a social climate that has to be taken into account. Prof. Mace considers with some justification that the failure to apply the results of research in the field of the human and social sciences is due mainly to the lack of professional men and technologists who combine experience and training in certain basic skills of application with the relevant basic scientific qualifications. But it is equally clear from discussions on productivity—even from that on higher technological education in relation to productivity to which Prof. Mace referred—that the attitude and understanding of labour as indicated by the trade unions is an important factor. The evidence of a change in this attitude provided by the support afforded by the Trades Union Congress to the work of the Anglo-American Council on Productivity, and the unanimity which has marked the reports coming from the productivity teams, is one of the most hopeful signs for the future.

Prof. Mace himself seems to recognize this factor, for it is implicit in the suggestion he makes for fundamental research into the basic conditions of 'status' and 'prestige'. Prof. Mace believes, for example, that it would be worth while to investigate thoroughly the reasons for the common belief in Great Britain that a career in applied science in industry is in some way inferior to that in other professions; but, in addition, he suggests that it would be worth studying carefully also what lies behind the apparent reluctance of university students, at particular times, to enter particular careers like teaching or industry. The historical reasons for the drift to particular occupations—to Whitehall, to

Harley Street, to the Inns of Court—are in part psychological reasons, and as such they require attention.

The relevance of Prof. Mace's address to the question of human relations in industry would thus have been sufficiently manifest had he not specifically referred to poor human relations between management and the factory being detrimental to co-operation in production, and to both industry and commerce suffering from poor public relations between business and the professions. His argument finds ample support both in the two pamphlets, "The Extent of Centralisation"[*] which the Acton Society Trust has since published in its series of studies of nationalized industry, and in the Beckly Social Service Lecture, "Christianity and Human Relations in Industry"[†], which Sir George Schuster delivered to the Methodist Conference in July.

Prof. Mace urged that psychologists have a special responsibility, first for the maintenance of the British tradition in the popularization of science, and second for the preservation of a common medium of communication. This duty of communicating understanding, above all to those who are concerned in any way with the management of men, is one of the most interesting points to be found in Sir George Schuster's analysis, from a Christian point of view, of human relations in industry. Sir George is as convinced as Prof. Mace of the imperative need for clear interpretation of scientific findings, as indeed of religious truths, in terms which can be understood by ordinary people. He will have no truck with the superficial. All the width of his experience as an industrialist, as chairman of the Sub-Committee on War Production of the Select Committee on National Expenditure, and as one of the 'working party' for the cotton textile industry and of the Panel on Human Factors of the Committee on Industrial Productivity gives authority to his statement of the case for enlightened management, and his plea both for the humanizing of management and for a fuller response from the trade union side.

The larger part of Sir George Schuster's lecture is concerned with the relationship of management to workers, and with the contribution which management can make towards establishing industrial employment as an essential part of a satisfying human life, in which there is sufficient scope for personal self-expression and personal responsibility. He insists that human values must not be sacrificed either to efficiency or inefficiency : efficiency, in fact, provides the real basis for confidence and co-operation, and this is no less true on the workers' side than on that of management. Efficiency, understood in the Greek sense of excellence, is an end itself.

As to the organization which will best secure such a purpose, Sir George Schuster has little to say beyond that every decision should be taken at the most effective level—the level where, as Mary Follett would have put it, the decision can be seen to be the demand of the situation ; and like Mary Follett and Elton Mayo, he believes that the most important problem in modern industrial organization is to discover the most appropriate working group for each organization. Of even deeper interest to the man of science are his observations on the way in which scientific study is improving working conditions, eliminating hazards to health and assisting to establish better relations between workers and management. Sir George is convinced that there is a wide field of study here, including not only industrial health in the broadest sense, the fitting of the job to the man and, conversely, the fitting, by selection and training, of men to the job, and the assessment of the job, but also human relations and human behaviour. In this connexion, scientific investigation could build up a body of knowledge of immense value for the increase of productivity and of industrial efficiency in the truest sense.

If such study, however, is to replace the subjective opinions and assumptions on which judgments and policies are now too frequently based, we must be on our guard against any tendency in such research to accept men merely as units for providing data for hypotheses and conclusions. Above all, in studying human relations and human behaviour, each individual must be treated with sympathy and understanding as a unique personality. The limitations as well as the possibilities of the scientific method have to be kept in mind.

Sir George Schuster's experience leaves him full of confidence that this intellectual approach can succeed. There is less resistance than even a generation ago, though the public interest in the scientific approach is not without misunderstanding as to what science can and cannot do. Moreover, he believes that success is possible without a complete change of the economic system, given the outlook and approach which he postulates on the side of the workers as well as on that of management.

The approach that Sir George advocates is obviously in harmony with Christian teaching ; but the distinction from scientific humanism in general is not manifest. Nevertheless, the Lecture shows how such a policy could contribute to the creation of the atmosphere in which right human relations are established. The first step must come from the side of management, but it cannot suffice without an adequate response on the workers' side. In insisting on the necessity for at least a philosophical, if not a religious, basis for a full life, Sir George roundly challenges the inadequacy of the materialistic outlook which has shipwrecked so many promising ventures in industrial co-operation in the past. We need a sound moral attitude, and unless that is forthcoming the instruments which science provides for the increase of industrial productivity and raising of standards of living are as liable to be used for evil as for good. On this question of values, all our attempts to further co-operation in industry by joint consultation and other methods, no matter how much hard intellectual effort and scientific study are put into the study of concrete problems of industry, may well founder. Without general acceptance of a common scale of values, there can be no co-operation or common purpose.

---

[*] The Extent of Centralisation : a Discussion based on a Case Study in the Coal Industry. (Nationalised Industry Series 6 and 7.) Part 1. Pp. ii+20. Part 2. Pp. iii+21–44. (Claygate : Acton Society Trust, 1951.) 2s. each Part.

[†] Christianity and Human Relations in Industry. By Sir George Schuster. (Beckly Social Service Lecture.) Pp. 128. (London : Epworth Press, 1951.) 6s. 6d. net.

The analysis of the organization of the coal industry made by the Acton Society Trust points to much the same conclusions as are drawn by Sir George Schuster, as well as supporting Prof. Mace's observations on the importance of human relations, and particularly of status and the need for education. Behind the question of how far centralization or decentralization can wisely and efficiently be carried lies this fundamental problem of establishing the most effective working group or unit, on which Sir George lays such stress. The Acton Society Trust's study recognizes that the problems of decentralization are common to all large-scale organizations, though appearing with different intensity in different industries. It is, however, the informal and uncodified relations which cause the trouble, rather than the officially defined limits of authority.

The main conclusion drawn from the present study is, in fact, that decentralization is primarily a problem of the adjustment of human relationships, and it is urged, in accordance with Sir George Schuster's view, that further research in other industries such as electricity or transport is desirable. Attention is directed, however, to two basic errors of thinking about the organization of the nationalized industries. The first is the belief that there is a 'best way' of carrying out any specific task and that science can discover it. The specialist is then conceived as the man who can work out what the 'best way' is. Accordingly, if the pattern of organization is such that the best specialist is put at its peak and consulted on everything, the undertaking will be run in the best possible manner. This assumption leads both to the construction of organizations of maximum size and to the imposition of uniform practices throughout those organizations. This view is based on a popular misconception of the natural sciences, and embodies just that habit of thought in the application of science against which Sir George gives so firm a warning. In the coal industry it is responsible for exceptional difficulties, partly because, while reorganization was urgently needed, experience in using specialists was considerably lacking, and there was also an acute shortage of specialists.

This is the feature of the study which is of most immediate interest here. Its discussion was indeed confined to the use of technical specialists in production, but this section of the study deserves careful examination by those concerned with the most effective use of the scientific worker or technologist in industry generally. Even if the difficulties are particularly acute in the coal industry for the reasons indicated, the nature of the relations between the operational or works manager and technical specialists of higher status, diffusion of authority resulting from the number of such specialists and from the number of stages in the management hierarchy, as well as the character and extent of the control and supervision exercised by higher management over lower management, all involve problems which require solution before high productivity can be expected. This brief discussion by the Acton Society Trust brings out very clearly the need for further thought as to the adequacy of the staff and line system in industry, on the definition of responsibility, and the need for much more forethought in the launching of large new projects involving new methods of operating. It is to be hoped that these problems of large-scale organization will not escape the notice of the British Institute of Management.

The second error of thinking relates to decentralization. It is assumed that an ideal compromise can be found which will make the best of both worlds, giving the plant or works manager freedom without sacrificing the advantages of scale. It may be, however, so the Acton Society Trust points out, that a compromise only provides the worst of both worlds, leaving the manager handicapped without achieving the technical advantages supposed to accrue from size. If that is so, a decision in favour of one extreme or the other would be necessary; but there may be room here also for further investigation. Such investigation must, however, keep clearly in mind the point made so strongly by Sir George Schuster regarding the importance of respecting human personality. That is no less important in considering changes in organization which affect the manager or the technologist than in considering conditions which affect workers on a lower level, and this latest study from the Acton Society Trust is implicitly as firm a protest against the purely materialistic or economic treatment of industrial problems as Prof. Mace's address on psychology and the laity or Sir George Schuster's Beckly Lecture. What is said about the importance of status in connexion with the colliery manager, and the recognition that the problem is at least as much one of education as of organization, sufficiently illustrate this, and have implications for other scientific and technical workers which suggest that professional bodies might well give careful consideration to these pamphlets.

CHEMISTRY OF THE EARTH

Geochemistry

By Dr. Kalervo Rankama and Prof. Th. G. Sahama. Pp. xvi+912. (Chicago: University of Chicago Press; London: Cambridge University Press, 1950.) 112s. 6d.

THE last important book in English on geochemistry, F. W. Clarke's "The Data of Geochemistry", first published in 1908, was also the earliest in this field of science which serves as intermediary between chemistry and geology. Since the third edition of Clarke appeared, major contributions have come from Vernadsky and Fersman in Russia, from Scandinavia, and especially from V. M. Goldschmidt of Oslo and Göttingen and his co-workers. Moreover, chemistry itself has made great new strides, especially, on the theoretical side, in the direction of radiochemistry, and on the practical side, in the application of spectrography and spectrometry to problems of analysis and separation. The earth is now to be understood in terms not merely of 96 elements, but also of 272 stable and 23 longest-lived unstable nuclides. The time is certainly ripe for a treatment in English on the subject, and this comprehensive work by Rankama, of Helsinki and Chicago, and Sahama, of Helsinki, is one of first importance both for geologists and chemists.

The authors accept the threefold task of geochemistry as defined by Goldschmidt: to establish the abundance relationships of elements and nuclides in the earth; to account for the distribution of elements in the various terrestrial spheres; and to determine the laws governing the abundance and distribution of the elements. The book is divided into two parts, the first dealing with the general laws and regularities which determine the abundance and manner of occurrence of the elements, and the second considering the elements one by one.

In Part 1 the determination of abundance figures largely. On this subject it is difficult not to feel some misgivings about possible errors of sampling which might have a serious influence upon the conclusions reached. It might be asked, for example, whether 5,159 analyses, even when weighted according to superficial areas of rock-types, are sufficient to assess the composition of so large a subject as the lithosphere, particularly when the tendency for petrologists to collect specimens of only a few pounds or even ounces in weight is remembered. Similarly, it seems very doubtful whether the "average meteorite" has any fundamental significance. If any criticism of this excellent book is justified, it is that the formidable tables of abundance data give an impression of finality which more detailed investigation may perhaps prove to be misleading. A chapter on the geochemical structure of the earth deals chiefly with hypotheses originated by the geochemists Washington and Goldschmidt; the exclusion from this discussion of the numerous alternative views advocated by geophysicists (apart from a brief consideration of Kuhn and Rittmann's revolutionary ideas) is presumably deliberate and, for the purpose of the book, probably wise; the nature of the subcrustal layers and of the core remains a speculative subject and not open to direct geochemical observation. The spheres which are open to direct observation —the upper lithosphere, the hydrosphere, the atmosphere and the biosphere—receive very adequate treatment.

The elements which enter into the composition of the lithosphere are divided into oxyphile (the petrogenic elements of Washington) and sulphophile. A discussion of crystal chemistry follows, based upon the useful structural classification of the silicates advocated by Hugo Strunz, and this leads to a thoroughly modern account of the rock-forming minerals. Magma, not migma, is regarded as the basis for the crystallization of the important minerals, and the authors state their faith when they say ". . . notwithstanding the geological significance of the igneous-looking rocks formed by metasomatic infiltration and recrystallization processes . . . the phenomena connected with the crystallization of a rock melt are fundamentally important". This compromise has much to recommend it. The conception of a major endogenic cycle (rock-melt–igneous rocks–sediments–metamorphics–migmatites–rock melt) springs from it.

A minor cycle involving exogenic processes is also usefully recognized as underlying the formation of the sedimentary rocks. Here the geological reader will find unfamiliar terms such as resistates (clastic sediments), hydrolysates (clays, shales, bauxites), oxidates (iron–manganese ores), reduzates (sedimentary sulphides), precipitates (calcium and magnesium carbonates), evaporates (the evaporites of current mineral literature) and bioliths (organic sediments), the whole providing a system of sedimentary chemistry.

In Part 2 the individual elements are treated in accordance with a rigid plan under which abundance in rocks and meteorites is stated, occurrence in primary and secondary minerals in various spheres is considered, and a cycle of transition is deduced in most cases. Concentration into deposits of economic value is referred to here.

This book may well be hailed as a major contribution both to geology and chemistry, and it should have an important influence on workers in those fields where the two subjects converge.

DEMOCRATIC PLANNING AND LIBERTY

Freedom, Power and Democratic Planning

By Karl Mannheim. Edited by Hans Gerth and Ernest K. Bramstedt. (International Library of Sociology and Social Reconstruction.) Pp. xxiv+384. (London: Routledge and Kegan Paul, Ltd., 1951.) 25s. net.

The Logic of Liberty

Reflections and Rejoinders. By Prof. Michael Polanyi. (International Library of Sociology and Social Reconstruction.) Pp. viii+206. (London: Routledge and Kegan Paul, Ltd., 1951.) 15s. net.

"FREEDOM, Power and Democratic Planning" concludes the studies of the theory and practice of sociology which Dr. K. Mannheim first expounded in "Ideology and Utopia" and continued in "Man and Society in an Age of Reconstruction". Like his earlier books, this posthumous volume is not always as clear in its treatment as might be desired, and here, far more than in the earlier books, the writing is marred by jargon which obstructs the argument and in the latter chapters even obscures the meaning. This is most conspicuous when he deals with religion and philosophy and the integration of the social order. While it is evident that Dr. Mannheim believed that society cannot be held together except by ethical, moral or religious forces, no more than in his "Diagnosis of Our Time" does he succeed in conveying to the reader any clear idea of what he understands by religion.

That is a serious defect in a book, which, addressing itself to the development of happier arrangements for achieving social reforms, establishes clearly the necessity for some spiritual or ethical basis such as the Western tradition and the acceptance of such values if a coherent society is to exist. It is the more unfortunate because for all the jargon, indifferent style and sometimes muddled thinking on certain topics, the book gives a picture of what is likely to happen to our society, and it is often both stimulating and suggestive. In spite of its faults it is an important book which directs attention to subjects which require careful thought and more objective study than they commonly receive.

Mannheim believed that freedom is impossible without the continuance of free institutions, but that the institutions which have served us in the past require modification if they are to be effective for the preservation of freedom to-day. In what he called creative politics—or the creation or evolution and use of the appropriate institutions—planning has its place, although with Mannheim central planning was essential only in regard to certain basic issues of policy. Government and the community are not separate entities and he looked to the organized group to give to the individual the opportunity to express his personality, while the activities of the groups are broadly co-ordinated in the interests of the community as a whole by the central authority.

For this to be possible, there must be a degree of social unity such as was achieved with our existing institutions in time of war. In time of peace this involves, first, re-shaping institutions so that power may be brought under democratic control; next Prof. Mannheim postulated the fostering by more adequate social education of democratic behaviour and personality to inculcate co-operation and tolerance; and third, the re-definition of values and re-discovery of an ethic generally shared to be found in what he describes as a 'dynamic religion'. On the defects of existing institutions Mannheim wrote shrewdly, and his criticisms and observations on such matters as the selection and training of leaders, the dangers of levelling down, the problem of loyalty, the position and functions of the Civil Service, the Press or broadcasting, and functions and relations of organized groups to society as a whole are often illuminating as well as wise. He understood, too, the limits as well as the dangers of some of the new techniques, and while he recognized their value he insisted that by themselves they offer no solution to the problem of power.

Some of his comments here recall Mr. Charles Morgan's recent emphasis on the dangers of the control or changing of human personality to which such techniques now expose us, but Mannheim is no more constructive than Morgan and some of his proposals are unconvincing. He appears to be over-confident as to the possibility of transforming men and institutions, and leaves his readers at least in some doubt as to whether his restraints and moderating influences will suffice.

For this there are probably two reasons. First, in espect of the re-shaping of institutions, he does not eally feel the problems of the conflict that inevitably ccompanies the disturbance of privilege and tradiional patterns. His discussion rarely goes as deep as that of Sir Ernest Barker in his "Reflections on Government", and on the institutional side there is little to be found here that was not implicit or xplicit in that book of nine years earlier.

The second reason is Mannheim's failure to convey any clear idea of what he understands by a dynamic religion. If some ethic or religion is to supply a ement which will hold the fabric of society together and give it unity, that ethic or religion must be xpressed clearly enough to fire the imagination of men and women and claim not merely intellectual assent but also something of the moral fervour or assion that has marked all the great cultural or religious revivals of the past. For that the sincerity f this book, the clarity of its diagnosis, are insufficient. When he wrote, Mannheim himself appears to have been still groping for the faith, for the spiritual basis which he recognized as essential if the atrophy of Western civilization is to be arrested nd men are to recapture that sense of purpose, that vision of greatness, required for the re-shaping of its nstitutions.

"New Ideas," wrote Mannheim, "always have originated in small groups with enduring personal contacts. . . . It is still the dissenting small group that favours inspired adventures of the mind and intellectual enthusiasm." This passage, in which he urged that such intellectual oases are the natural and only protection of society to-day from the deadening uniformity which propaganda tends to impose, provides a natural link with those reflexions and rejoinders on the theme of liberty which Polanyi has collected under the title "The Logic of Liberty". The essays, indeed, are not new, but through them runs the same theme of the vulnerability of freedom, the necessity for a fresh defence in this troubled period of history and for a re-assertion of ideals which we have allowed to become discredited.

Pólanyi is concerned primarily with the defence of science, but this he insists is part of the defence of our civilization. The forces undermining the position of science are a detachment of those assailing our whole civilization, and when he claims for science the respect due to it as a cultural and moral value he is repudiating as firmly as Mannheim the adequacy of a purely materialistic basis for civilization. This, far more than his re-assertion of the incompatibility of planning or directed research with the freedom which is the very essence of science as a vital activity, the search for truth and an example of the good life, is the keynote of the book, and it would be unfortunate if his shrewd attack on planning and exposition of the limitations in any way obscured this wholehearted challenge to the materialistic thesis.

Throughout the book, Polanyi emphasizes that liberty is conditioned by society and that the freedom in which science develops is a form of intellectual liberty, while economic liberty he regards as a kind of technique. Polanyi is easiest to follow in this first part of the book, where he deals with the example of science and is here even more suggestive than Mannheim as to the way in which small groups or professional institutions can contribute to the building up and safeguarding of a free society. His exposition of an engineering or physical approach to economics is more difficult for a layman to follow, and its value appears to be less constructive. He is more effective in disposing of the pretensions of central planning than in concrete suggestions as to how liberty is to be defended.

The great value of these two books is that they do not merely defend freedom: they assume the offensive and attack the ideas that lie at the basis of those forces or institutions which to-day threaten the free society. Both writers have the courage of their conviction that a free society is a true end in itself—a body of men who respect truth, desire justice and love their fellows—and that accordingly it may rightly demand the services of its members in upholding its institutions; and, as already noted, where Polanyi deals specifically with the freedom of science itself, it is as a part of the larger problem. Scientific beliefs, in his view, are part of the beliefs cultivated in a free society and accepted by its members.

Polanyi's argument that the scientific worker should not limit himself to the defence of freedom of science as such but should play his part in the defence of the free society in which alone science can fully function, carries, however, the corollary that there should be a much clearer understanding in the community as a whole of what science really is, and how it works to widen the understanding of Nature necessary to all men. That academic freedom can claim to be an efficient form of organization for discovery in all fields of systematic study controlled by a tradition of intellectual discipline has its implications outside the strictly scientific field and especially in relation to what Polanyi describes as the achievement of spontaneous order. So, too, inasmuch as freedom of science, like freedom of worship or freedom of thought in general, can be described as a public institution by which society opens to its members the opportunity for serving aims that are purposes in themselves, the way in which the mutual co-ordination of scientific activities is achieved within the field of science itself by consultation, competition and persuasion bears closely on the evolution of the new forms of organization and means of social adjustment which Mannheim sought.

There is much, indeed, in both these books to stimulate the thinking among professional men which is required to safeguard freedom to-day. They represent one group which has an indispensable part to play, not the less because of the inherent tendency of all professional bodies or associations to become conservative or ossified. They, of all men, need to keep in mind the warning from the sixteenth century: "There never was anything by the wit of men so well devised, or so sure established, which in continuance of time hath not been corrupted". R. Brightman

UNIVERSITY OF MANCHESTER, 1851–1951

Portrait of a University, 1851–1951

To Commemorate the Centenary of Manchester University. By Prof. H. B. Charlton. Pp. x+185+23 plates. (Manchester: Manchester University Press, 1951.) 15s. net.

One reviewer of this book has complained because Prof. H. B. Charlton did not write a full, systematic history of the University of Manchester. Evidently, he did not know Prof. Charlton—the last person to try to produce such a thing on any occasion. On the occasion of a centenary it would have been wrong to try. Instead, he has done something more difficult, which he alone could do, and which will be far more useful to future historians of Manchester and other universities. He has done precisely what the title of the book claims. One hundred years is not long in the life of an institution, so that it is possible to depict it as a unity during that time. But one hundred years, in these migratory times, is almost immeasurably beyond the span of one man's memory. Prof. Charlton has an academic memory far longer than most, for he has been on the staff of the University of Manchester for very nearly forty years. Not only has he seen and taken part in all that has happened since the First World War, but also he knew the leading men of the previous period when Manchester was emerging as a complete university. (In parenthesis: though Owens College ceased to exist legally in 1904, its name still came easily to the ordinary man in the Manchester street thirty years later, whereas the name 'University' meant little and the title 'Victoria' nothing.) Charlton is fortunate, too, in earlier historians. Edward Fiddes, for long a colleague of his, whose actual acquaintance with the University went back to 1890, wrote its history up to 1914. There is also a valuable account of Owens College up to 1886 by Joseph Thompson.

The main theme of this book is: What were the aims of the founders and initiators, and in what manner have they been fulfilled? Prof. Charlton distinguishes four stages in the process. The early stage was that of the old Owens College in its cramped quarters in Quay Street, with its sixty or seventy students and its half-dozen professors, each teaching two if not three subjects. (To be exact, on the photograph opposite p. 16 there are eight professors; they are less bewhiskered and bearded than one would expect, perhaps because they were rather young.) The next stage was the move to the new site in Oxford Road, soon discovered to be too small, the incorporation of the Medical School, older than Owens, and the foundation of a federal university, with Liverpool and Leeds as partners. In the third stage came the attainment of full university status; and then the modern period, with, now, nearly six thousand students, including those in medicine and technology, and a teaching staff of more than eight hundred. Incidentally, the book is well equipped with statistical data, plans and illustrations.

In claiming that the aims of the founder have been and are being fulfilled, Prof. Charlton has to make a very interesting qualification. Robert Owens wrote in his will that the college was to be for the education of "young persons of male sex", and we can only guess what he would have thought of the thousand or more young persons of female sex now studying there. In 1845 when he died there could as yet be no question of higher education for women, since there was next to nothing of secondary education for them; indeed, there was not too much for their brothers. A quarter of a century later, conditions had changed, the question did arise and Parliamentary sanction was obtained to set aside the restriction. However, Manchester acted on it extremely cautiously. If there was too much delay in admitting women, particularly into the Medical School, there has been compensation since. Assuming that Owens was hostile to the higher education of women (we do not know that he was), he would have been instantly converted on being introduced to the first lady who occupied a chair and the two who have followed her. Edward Fiddes's account of this whole controversy is reprinted in an appendix.

Robert Owens, and his friends and successors who took the first steps, wished to foster higher education, and in doing so to serve the special interests of Manchester and its neighbourhood. Young people need to have their minds enlarged and elevated; they also need to earn a living, and can do that best by pursuing effectively the normal activities of the community they live in. On the narrowest interpretation of technical efficiency, the practitioner is none the worse if he grasps the principles underlying his practice or even knows something about other things also.

Prof. Charlton quotes a number of statements of university aims and methods from earlier members of Owens College, from Ward, Roscoe, Schuster and Tout; he also does a valuable service in printing in full Samuel Alexander's essay, written in 1931 which begins: "I should describe a university as an association or corporation of scholars and teachers engaged in acquiring, communicating, or advancing knowledge, pursuing in a liberal spirit the various sciences which are a preparation for the professions or higher occupations of life. The omission of any part of this description would convey a false impression of what a university is. It does not exist only for acquiring or communicating the higher branches of knowledge, but for extending them as well; and it does not only pursue the sciences for their own sake, but, so far as the larger part of its members are concerned, pursues them in preparation for the professions. I had almost said that the purpose of a university was to prepare for the professions, and I should be ready to defend this, provided that the qualifying words, 'in a liberal spirit', are not merely not omitted but emphasized." It is tempting to go on quoting from one who did so much within the University of Manchester and outside to demonstrate what is meant by 'a liberal spirit'. A. D. Ritchie

LAW OF COPYRIGHT AND INDUSTRIAL DESIGNS

Copyright and Industrial Designs

By A. D. Russell-Clarke. Pp. xv+262. (London: Sweet and Maxwell, Ltd., 1951.) 37*s.* 6*d.* net.

THIS book embodies all aspects of copyright, whether literary, dramatic, musical or artistic, together with copyright in industrial designs. It is the first of its kind to include all these branches of copyright. The author is to be congratulated upon the lucidity and practical manner with which he deals with the difficult questions in the field covered by the Copyright Act of 1911 and the Registered Designs Act, 1949. Prior to the coming into operation of the Designs Act, 1949, copyright in industrial designs was largely associated with the patent law rather than the copyright law. In 1947 the departmental committee, set up under the chairmanship of Sir Kenneth Swan to inquire into the working of the Patent and Designs Acts, recommended a number of changes of the law relating to designs. As a result of these changes, it has been made clearer that the law of copyright in industrial designs has a closer affinity to the law of literary copyright than to the law of patents.

The first part of the book is devoted to a detailed examination of the Copyright Act of 1911, in relation to literary, dramatic, musical and artistic work. The author points out the remedies available to copyright owners, and two chapters are usefully devoted to questions of licences and publishing and other agreements. At a time when publishers appear to be inclined to remunerate authors of technical books at the lowest possible rates, the suggestions contained in this part of the book are likely to be of some help. A chapter is devoted to miscellaneous matters such as the term of copyright, University Copyright and Crown Copyright.

Part 3 of the book concerns the Registered Designs Act, 1949, which came into force in January 1950. So far there have been very few reported cases under this Act which have anything at all to do with designs. The author deals with the nature of the design, its publication, the available remedies for its infringement and the procedure for applying for registration at the Patent Office whereby copyright may be obtained for a period of up to fifteen years. Part 4 deals with cases of overlapping which occur between the Copyright Act and the Designs Act.

The book is well indexed, and the fact that neither of the two Acts is set out in full has assisted in keeping the price and the size reasonable. It is certainly a book which should prove of great assistance not only to practitioners, but also to members of the technical staff of firms, designers and authors. R. G. Lloyd

SOCIETY UNDER THE MICROSCOPE

Social Surveys and Social Action

By Mark Abrams. (Contemporary Science Books.) Pp. v+153. (London: William Heinemann, Ltd., 1951.) 8*s.* 6*d.* net.

IN this little book Mr. Mark Abrams starts with the emergence of Booth and Rowntree, the pioneers, and shows what has developed out of their pioneering experiments. He is concerned with the social survey, not as an instrument of fundamental research, but as a form of investigation used in the twentieth century to assist in the identification and quantitative analysis of social problems which call for social action. He traces the development from poverty studies to a wide range of inquiries directed to matters in which questions can be more exactly related to the needs of social policy—nutrition, old people and town planning—and he explains how the Second World War led the British Government to start its own survey department and how companies specializing in survey work arose and have been increasingly employed to make investigations on behalf of public authorities and private agencies. These are the direct descendants of the pioneers. In addition, there are the 'borrowers'—market research and public opinion polls. Finally, Mr. Abrams discusses the role of the social survey in the Welfare State, and has some interesting things to say about the way in which surveys might help to discover how to make public communications intelligible to the masses. This is a worthy aim provided one does not forget the complementary process of making the masses sufficiently intelligent to understand the communications.

Thus the reader is given a genealogy which will be helpful to the novice; but that is not enough to satisfy the serious student, and the book as a whole is disappointing, although the subject is fascinating and the author an acknowledged expert. With such limited space at his disposal, the author could achieve success only by selecting a narrowly defined theme and sticking to it. He has, by a narrow margin, failed to do this. A chapter is devoted to the historical antecedents of the pioneers, and it treats familiar material in a rather crude manner. Another chapter gives an account of social surveys in the United States and is too sketchy to have much value. The author would have done better to fill out his descriptive picture of survey organizations in Great Britain at the present time. A better balance would have been obtained if he had devoted less space to Mass Observation and had found room to mention such organizations as the British Institute of Public Opinion and the National Institute of Economic and Social Research.

If we assume that Mr. Abrams's theme is the social survey as an application of scientific method to the handling of practical social problems, then we should expect to be taken rather further on three points: first, the grounds for claiming that the survey method can be truly scientific; secondly, the respective roles of routine official collections of data and of *ad hoc* surveys; and thirdly, the extent to which the results of social surveys can, and do, point unequivocally to particular forms of social action and the point at which political judgment must enter. All these points are mentioned; but the argument is not sufficiently firmly pulled together to leave a clear impression on the mind of the reader.

T. H. Marshall

The Infinite in Giordano Bruno

By Sidney Greenberg. With a translation of his Dialogue, Concerning the Cause Principle, and One. Pp. ix+203. (New York: King's Crown Press; London: Oxford University Press, 1950.) 20s. net.

THIS erudite contribution to our knowledge of the works of Bruno the Nolan is one of the latest examples of the value of the policy adopted by the King's Crown Press in making specialist studies available to scholars at a very reasonable cost. The volume divides naturally into two—the place of the infinite in Giordano's system, and a translation of the "De la Causa" into English. (Incidentally, there seems to be a comma missing from the title-page, which makes the full, and very noble, phraseology read rather oddly.)

Broadly, these massive writings are, as the author states, the outcome of Bruno's striving to "comprehend the Universe". At the same time, allowing for the tensions inseparable from the onset of humanist philosophies, it is not surprising that much heat was generated *en route*, and that only comparatively recently has this one-time Dominican monk come into his own. We are beginning to realize more explicitly nowadays that the *ordo essendi* is seldom the *ordo cognoscendi*. Meanwhile, Dr. S. Greenberg's reference to Gilson (p. 15) gains added weight if the original setting is consulted. For there, 'good' is contrasted with 'Being': a limitation is implicit in the former, but not in the latter, which is why the Greek 'infinity' was always coupled with imperfection.

English-speaking students will be grateful for being enabled to follow Bruno's great work of 1584 the more readily, and thus to appreciate some of the qualities of that tempestuous intellect.

F. I. G. Rawlins

Die botanische Buchillustration

Ihre Geschichte und Bibliographie. Von Claus Nissen. Band 1: Geschichte, Lieferung 1. Pp. vii+80. Band 2: Bibliographie, Lieferung 1. Pp. vii+80. (Stuttgart: Hiersemann Verlagsgesellschaft m.b.H., 1951.) n.p.

IN the drawing and painting of plants—especially of flowers—art and science meet, sometimes overlap and occasionally combine. The diversity and beauty of form and colour to be found in the plant kingdom attract the artist, while the botanist often finds accurate representation in black-and-white or in colour more valuable as a record of his studies than verbal description. The best botanical artists have combined in their work the feeling of beauty with the accuracy of detail demanded by the man of science. Lately, there has been an increased interest in the history of botanical illustration, an interest apparently not confined to Great Britain.

It is impossible fully to judge the value of C. Nissen's work from Part 1 of Volume 1 and Part 1 of Volume 2. The first volume is to deal with the history of the subject. Its first part contains a brief introduction dealing with some aspects of technique and consideration of botanical illustration in ancient times, the Middle Ages, the period of early printing, the Renaissance, and the Baroque Period (in part). The second volume is, in the first part, strictly bibliographical (authors *A* to *He*). Since there is at present no scheme of contents, it would be unfair to criticize the scope and arrangement of the work from the two parts. There appear, however, to be a number of surprising omissions. Thus, under William Curtis one would expect to find some information about the *Botanical Magazine*. Again, under H. N. Dixon there is no mention of the third (1924) edition of "The Student's Handbook of British Mosses".

The many references provided in both parts should be of considerable interest and use to all who study the history of botany. It is to be hoped that a good index will be provided.

W. B. Turrill

Fourier Methods

By Prof. Philip Franklin. Pp. x+289. (London: McGraw-Hill Publishing Co., Ltd., 1949.) 34s.

PROF. PHILIP FRANKLIN surveys a wide field, interpreting the phrase of his title as covering any method which analyses or synthesizes a function by means of periodic components. He is writing for the technologist, and illustrates plentifully from the field of mathematical physics, but is content to quote the fundamental theorems of pure mathematics which he requires. References to the mathematical theory and for further reading are given.

The first chapter deals with the elements of the theory of complex numbers, with applications to impedances. The second chapter describes the Fourier series and the Fourier integral, including a summary of twelve-ordinate harmonic analysis, the third studies partial differential equations, and the fourth boundary values problems, particularly those arising in heat conduction and in transmission lines. In the last chapter the Laplace transform is briefly described and applied to problems of electric circuits and transmission lines. There is a full supply of worked examples, and an excellent collection of elementary exercises for the reader, with answers.

The treatment is clear, but since so much is dealt with in a comparatively small book, it is never profound. The book would thus serve to introduce the young student to a wide field of knowledge, without requiring anything more than a grasp of elementary calculus as a prerequisite. But it is only an introduction, and the suggestions for further reading should be taken seriously.

The Life of a University

By Basil Cottle and J. W. Sherborne. (Published for the University of Bristol.) Pp. vi+116 (50 plates). (Bristol: J. W. Arrowsmith, Ltd., 1951.) Paper, 6s. net; cloth, 10s. 6d. net.

THIS brochure is a well-written sketch of the growth and organization of the University of Bristol and some institutions connected with the University. There are some fine illustrations; but the title of the book is not happily chosen. Rather less than half of the book is occupied by a short history of the University, the remainder sketching the organization and present activities. It is thus less an account of the life of a university than of its growth and structure, being purely descriptive. Although entirely different in form, it covers essentially the same ground as the pamphlet "An Introduction to a University" put out by the University of Birmingham, but is scarcely so well designed as the latter pamphlet to guide those who are facing a decision as to whether to enter a university at all. The "Life of a University" appears to be designed, on the contrary, for past or present members of the University of Bristol itself, whether students or staff, and to them it may be further commended for the excellence of its general production.

ARTIFICIAL ACCELERATION OF ATOMIC PARTICLES*

By Prof. O. R. FRISCH, O.B.E., F.R.S.
Cavendish Laboratory, Cambridge

THE progress of nuclear physics in the past two decades has depended greatly on the use of machines for producing high-energy particles; these fast particles are used for bombarding atomic nuclei with the aim of producing nuclear transformations. Though the first machines were built nearly twenty years ago, much still remains to be known about the atom. It must be remembered that we know to-day about nine hundred different kinds of atomic nuclei; only three hundred of them are found in Nature, while the remainder have to be prepared artificially, using either high-energy particles or neutrons coming from a nuclear pile. Furthermore, each of these nuclei is a complicated structure, with features many of which are still not understood. Finally, quite new phenomena have been recently discovered, such as the artificial creation of mesons in high-energy nuclear collisions. These mesons, previously found only in the cosmic radiation, can now be studied much more closely, and their study is thought to bear closely on the riddle of the 'nuclear forces', the forces whereby the particles in an atomic nucleus are held together.

Considering the use of fast particles for splitting atoms, it must be remembered that nearly the whole weight of an atom is contained in its nucleus, in size a minute fraction of the atom; all the rest is a tenuous cloud of electrons moving around the nucleus at great speed. Removal of a few of these electrons does not constitute atom splitting; it happens in many chemical reactions, in flames and even in friction, as when glass or ebonite becomes electrified by rubbing. The arrangement and motion of those electrons follow the laws of quantum theory and are, on the whole, so well understood that it is possible, in principle, to compute beforehand the physical and chemical properties of a new chemical compound, though the calculations are usually hopelessly complicated.

Of the structure of atomic nuclei far less is known. Their sizes and their electric and magnetic properties can be measured, but give only indirect evidence of internal structure. In order to learn about the parts of a nucleus and how they are held together, we must break up the nucleus, and the most suitable tool is another nucleus, preferably a smaller one. Such a particle is fired with great speed at the nucleus to be broken up. Of course, we cannot take aim: we have to fire a great many shots at random and hope that some will score. Passing through any given atom, such a nuclear bullet has only a minute chance—perhaps one in a hundred million—of hitting its nucleus, but it can pass through many thousand atoms in succession. Thin aluminium foil—the so-called 'silver paper'—contains about a hundred thousand layers of atoms; on passing through this foil, a nuclear bullet has about one chance in a thousand of hitting an aluminium nucleus. By using many millions of bullets a respectable number of hits can be achieved without any marksmanship whatever.

There are two reasons why bullets of high energy, that is, very fast ones, have to be used: the bullet must be able to break through the electronic shells of many thousand atoms; and it must be able to overcome the electric repulsion which it experiences on approaching another nucleus, caused by the positive electric charge which they both carry. This repulsive force gets very large; for example, an alpha-particle—that is, a helium nucleus—almost touching a uranium nucleus gets pushed away with a force of nearly a hundredweight. Such force represents a kind of barrier through which the bullet has to break before it can touch the nucleus, and the size of this barrier corresponds to the electric potential at the surface of the nucleus. This potential can be easily calculated, from the known size and electric charge of the nucleus. For example, the potentials on the surface of nuclei of carbon, copper and uranium are 2·6, 7 and 15 million volts respectively. Thus, nuclear bullets have to be accelerated with potentials of the order of several million volts in order to enable them to enter an average atomic nucleus.

Potentials of several million volts are not easy to produce or to handle, but generators for potentials up to about four million volts have been built and are being used by nuclear physicists. They usually follow a design by Van de Graaff and employ a fast-moving belt to carry electric charge to the high-voltage electrode, much as a belt-conveyor carries gravel or coal to a higher level. Ions are produced by an electric discharge and are then driven through the accelerating tube to a target at ground potential containing the nuclei to be bombarded. To delay the onset of sparking, the whole arrangement is usually placed in a boiler-like container which can be filled with compressed air or nitrogen. Because of their limited voltage, these electrostatic generators are useful for attacking light nuclei only—that is, elements in the Periodical Table up to, say, calcium. On the other hand, they are very suitable for precision work since they can be stabilized so that the voltage varies by less than one part in ten thousand; this is important because some of the phenomena caused by nuclear bombardment depend extremely sharply on the bombarding energy, that is, on the accelerating voltage.

For the acceleration of particles to much higher energies, the principle of multiple acceleration has been developed, whereby a comparatively small voltage is applied to the same particle a number of times. The first multiple accelerator was built by E. O. Lawrence and D. H. Sloan in 1930. It consisted of a number of metal tubes, all lined up in an evacuated container, and connected alternately to the terminals of a high-frequency generator of alternating electric potential. The length of the tubes was chosen such that a particle which had been accelerated on entering a tube would again be accelerated on leaving it, the potential having changed sign in the meantime. In this way they succeeded in accelerating mercury ions to energies of 90,000 volts, merely to show that the method would work, and well knowing that such mercury ions are useless for nuclear disintegration work. The chief difficulty of extending that method to lighter particles and higher energies lies in the great speeds involved. For example, a proton, that is, a hydrogen nucleus, which has been accelerated by a potential of five million volts—or by an equivalent repeated application of smaller voltages—will have a speed of about 17,000 miles per second. Even if we allow that its average speed during acceleration is somewhat lower, it will travel fifty feet in one-millionth of a second. During this short time the electric potential must change a number of times if we are to get any real benefit from the multiple acceleration principle. In other words, we have to apply an electric potential which changes many million times in a second, as in a short-wave radio transmitter, and such transmitters, with the required power, did not exist in 1930.

---

* Substance of a Friday Evening Discourse at the Royal Institution, delivered on May 11.

In order to accelerate protons to several million volts, Lawrence had to use a much longer path, of many hundred feet, and in order that the apparatus should be of manageable size he made the particles follow a circular path. The principle can be illustrated by a crude model in which there is a horizontal circular rail, pivoted so that it can be slightly tilted one way or the other, and by suitable manipulation a steel ball can be made to go round faster and faster until it jumps from the rail on account of its centrifugal force. To make a charged particle follow a circular path, a magnet is used. If a particle moves at right angles to the magnetic lines of force it will be pushed sideways at right angles to the lines and to its direction of motion; and, if the field is uniform, it will describe a circle in a plane perpendicular to the lines of force. The diameter of the circle is inversely proportional to the strength of the field and proportional to the speed of the particle; this latter fact is of decisive importance because it means that a particle always takes the same time for one circuit, whether its speed be high or low. Although at extremely high speeds, approaching that of light, this is no longer true, when Lawrence and Livingston built their first 'multiple magnetic resonance accelerator', or cyclotron as it was nicknamed, the constant time for one circuit greatly eased their task of design.

To produce economically the strong and extended magnetic field which is needed, one employs an electromagnet consisting of a suitably shaped core of soft steel surrounded by coils through which an electric current is passed. Its shape can be derived from two horseshoe magnets by appropriate deformation. Between the two horizontal circular pole-faces, where a fairly uniform magnetic field exists, the tank is inserted and thoroughly evacuated by continuously operating pumps so that the protons to be accelerated can move freely. The electric accelerating field is usually made between two hollow electrodes called 'dees' (because they are shaped like a D), which are connected to a short-wave generator with the power of a medium-sized radio transmitter and working at a frequency adjusted accurately so that the voltage changes sign in step with the protons going round. The protons, which are produced near the centre by passing fast electrons through hydrogen gas, are then pushed back and forth by the electric field between the 'dees', and at the same time their path is bent by the magnetic field; thus each proton describes a path which looks like a spiral but is more nearly a succession of larger and larger semi-circles. The acceleration ends when the proton gets near the edge of the magnet; hence bigger magnets are needed to make faster protons, since the intensity of the magnetic field is limited by saturation of the steel. The fast protons can be utilized either by inserting a target into the tank so as to intercept the protons at the desired speed, or else an electrically charged deflexion-plate can be employed to persuade a fraction of the protons to leave the magnet in a tangential beam so that experiments can be more conveniently done away from the magnet.

The particles most usually accelerated by a cyclotron are protons and deuterons, the nuclei of ordinary and heavy hydrogen, respectively. Although the latter forms a rare admixture—about one part in five thousand—of natural hydrogen, it is fairly easily separated and is nowadays marketed by the ton for nuclear fission piles. A cyclotron accelerating deuterons uses a few ounces a year.

A deuteron is composed of a proton and a neutron, and if a beam of deuterons impinges on a target made of a light element, it often happens that the proton sticks to a nucleus while the neutron goes on. The target thus becomes a source of neutrons, and by choosing the target element and varying the speed of the deuterons, the speed of the resulting neutrons can be adjusted within fairly wide limits. This feature is still valuable, although for sheer numbers produced a fission pile is now a much superior neutron source.

The impact of the deuteron may also result in the emission, not of a neutron, but of a proton, an alpha-particle (a fast helium nucleus) or some other nucleus. The distribution in energy and angle of those particles emitted provides valuable clues to the structure of nuclei and is being intensively studied. Furthermore, the nucleus left behind may in many cases be one of those which are not found in Nature, because they are intrinsically unstable, that is, radioactive. Indeed, one of the most important applications of cyclotrons is the production of artificial radioactive substances, for, though many of them can be made more cheaply by neutron bombardment in a fission pile, others still need to be made in a cyclotron.

The construction of cyclotrons for energies substantially higher than, say, ten million volts is made difficult by the fact that the mass of the particles increases with increasing energy, in accordance with the laws of relativity theory, and that the time taken for one whole turn increases in the same proportion. A proton of ten million volts energy is one per cent heavier than a slow proton and hence takes one per cent longer for each turn; at this stage a proton can still make a number of turns before it gets out of step. But at a hundred million volts the difference is ten per cent, and also many more turns are needed to achieve acceleration to such an energy. This problem is aggravated by the need of shaping the pole-faces so that the magnetic field decreases slightly from the centre to the edge. Such a decrease causes the lines of force to bend like the staves of a barrel, and this in turn has a beneficial 'focusing' effect on the particles: it deflects them back to the mid-plane between the pole-faces if, by starting obliquely or by being slightly deflected in flight, they have started to move towards one of the pole-faces. Without this focusing, practically all the particles would strike one or the other pole-face long before they are fully accelerated.

When Lawrence, shortly before the Second World War, started to build a giant cyclotron with a magnet weighing 4,000 tons and pole-pieces 15 ft. in diameter, many people doubted that he would be able to accelerate protons up to the edge of that magnet. Yet it was done, by using a high-frequency generator with variable frequency, containing a tuning condenser driven by an electric motor, so that the frequency goes up and down a thousand times a second. Most of the time the frequency is wrong; protons may start, but get out of step after a few turns. However, once in each cycle, the frequency decreases through its 'correct' value, and then a swarm of protons starts spiralling outwards. As they get faster they gradually take longer for each turn, but the electric waves, too, get slower, so the protons can remain in step. No careful adjustment is needed: if the protons are accelerated too rapidly, they begin to get out of step, and that automatically reduces their acceleration so that the tuning condenser can catch up with them. This self-synchronizing feature is extremely valuable, and indeed this so-called synchro-cyclotron (also termed frequency-modulated cyclotron) is much easier to operate than an ordinary one, where the frequency has to be very carefully adjusted. The biggest synchro-cyclotron at present in operation is in Chicago and generates protons of nearly 500 million volts.

Not only fast nuclei but also fast electrons are of interest to the nuclear physicist. Being negatively charged, they are not repelled by nuclei; on the other hand, they are found to have very little effect on them. But fast electrons can be used for making hard X-rays, which are very suitable for putting a well-defined amount of energy into a nucleus.

Electrons are much lighter than protons—about 1,800 times lighter—and can thus be easily accelerated to speeds close to that of light. At three million volts, an electron has 99 per cent of the speed of light. Any further voltage produces scarcely any increase of speed, but merely an increase of mass: the electrons are 'aggravated' rather than accelerated—though the latter term is still generally used. This nearly constant speed means that electrons can be accelerated on a fixed circle by an electric field of fixed frequency, but the magnetic field which bends their path into a circle must be made to increase rapidly with time, to keep them to the same circle in spite of their growing energy. Again, the system turns out to be self-synchronizing, and it has become known as the synchrotron. It was invented about 1945 by Weksler in the U.S.S.R. and independently by E. McMillan in the United States, who also built the first big one, for about 300 million volts, after a small one had been built and operated in Great Britain.

The synchrotron is capable of reaching higher energies than the earlier and somewhat similar betatron; but with both machines the radiation of electromagnetic waves from the circulating electrons rises very rapidly with increasing energy and sets a practicable limit somewhere about 500 million volts. This difficulty is avoided if the electrons are accelerated in a straight line; such an arrangement harks back to Lawrence's first multiple linear accelerator, but, in the meantime, the development of radar has made possible the generation of much higher frequencies at much greater power.

A modern linear accelerator for electrons (a proton accelerator has been built, but seems to have no great advantages) consists of a long evacuated tube through which electrons are pushed along by electromagnetic waves, much as a surf-rider is propelled by ocean waves. In order to adjust the speed of the waves to the correct value, the interior of the tube is 'corrugated' by the insertion of numerous metal irises, accurately machined and spaced. Several pilot models have been built and operated in Great Britain during the past few years, and machines for medical use are now under construction. A large linear accelerator, designed for producing electrons of 1,000 million volts, is partly completed in Stanford, California.

The chief object of these extreme-energy machines is the production and study of mesons, particles intermediate in mass between the electron and the proton. Yukawa pointed out in 1935 that the short-range forces, known to exist between the parts of a nucleus, suggested the existence of such intermediate particles, about two hundred times heavier than electrons. This theory, now widely accepted, does not suggest that mesons are actually present in nuclei. Theoreticians, if pressed on that point, like to say that the particles in a nucleus are held together by the exchange of virtual mesons. It is difficult to picture a virtual meson; perhaps I may suggest that the relation between a real and a virtual meson is the same as between a £5 note and an I.O.U. Like the latter, a virtual meson has a limited circulation; it can be exchanged only between particles in the same nucleus, which are, so to speak, held together by their mutual debts. If a nucleus is hit by a particle from outside, bringing a lot of energy with it, this sudden affluence may enable one or more of the particles in the nucleus to settle their debts and to escape. If the energy is big enough—some 200–300 million volts—then a real meson may appear. Under bombardment at such energies, mesons are indeed observed, usually through the characteristic tracks they form in special photographic emulsions; these tracks are intermediate between the fairly straight tracks formed by protons and the thin and rather curly ones formed by electrons.

It should be stressed that the theory of mesons is much more definite and clear-cut than my general description may suggest. It makes definite predictions relating the known properties of nuclei to the as yet unknown properties of mesons. To test those predictions, we have to study the velocities with which mesons emerge from a nucleus struck, say, by a fast proton, the effect of proton speed on the speed and number of mesons created, the interaction of mesons with matter through which they pass, and so on. We know already that there are at least three kinds of mesons with different mass, each of them unstable and prone to transform itself within a small fraction of a second into a lighter meson or an electron, or even into two photons (quanta of electromagnetic radiation). Thus there is a whole new world to be explored, a world of ghostly, fast-moving, short-lived particles, at the very fringe of our everyday world and yet perhaps essential for our understanding of why ordinary matter is what it is.

PRESERVATION OF BIOLOGICAL MATERIALS BY FREEZE-DRYING

During June 29–30 the Institute of Biology held a symposium on "Freezing and Drying" in the rooms of the Royal Institution. The first session, with Dr. R. I. N. Greaves in the chair, was devoted to consideration of the industrial applications of freeze-drying and its use in the preservation of food. E. W. Flosdorf surveyed methods current in the United States for the preparation of materials for large-scale drying, including pre-freezing and freezing *in situ*, and for the supplying of heat to the drying product by circulating hot water, direct electrical heating or infra-red radiation. A variety of systems for vacuum maintenance are in use, including oil pumps in conjunction with mechanically refrigerated condensers or direct pumping of the water vapour with multi-stage steam ejector pumps. Materials now available commercially in frozen-dried state in the Western hemisphere include human blood products such as immune serum globulins, enzymes, vitamins, antitoxins, antibiotics, hormones, veterinary vaccines, laboratory biological reagents such as complement, and food products, coffee, pineapple juice, orange juice and raw ground beef.

Application of the method to the production of antibiotics was discussed by J. H. Singer. The problem of maintenance of sterility has been overcome by fitting the trays of antibiotic (either in vials, or in bulk) with metal lids which can be raised hydraulically within the desiccator chamber by outside control. Bulk-drying procedures have been adopted for streptomycin calcium chloride and dihydrostreptomycin sulphate. Sterility is maintained by filling sterile stainless-steel trays *in situ* with a dispensing device delivering the correct quantity of sterile solution.

The high cost of production will almost certainly prevent the commercial utilization of freeze-drying for food preservation, but R. Gane showed that such varied materials as sliced apple, fruit juices, liquid egg, meat and fish can be dried without much difficulty. Reconstitution of meat and fish tends to be difficult, however, if the pieces are more than 1 cm. thick. Vegetables, such as peas, with an impermeable skin cannot be frozen by evaporation and pre-freezing, and grinding is essential. The immediate value of freeze-drying applied to food lies in its preparation for biochemical analysis. The last paper in this session, by L. G. Beckett and A. S. D. Barrett, was a consideration of physical aspects of the design of freeze-drying equipment with reference especially to vacuum technology.

Papers given in the second session, with Sir Alexander Fleming in the chair, concerned the preservation of mammalian cells, avian tissues and whole organisms at low temperatures. P. B. Medawar and R. E. Billingham showed that Malpighian cells of the epidermis of rabbit's ear skin could survive either very rapid *or* very slow freezing. These cells in grafts soaked in Ringer's solution did not survive slow thawing. Survival could be obtained, however, if the Ringer's solution contained 15 per cent glycerol. Suspensions of isolated epidermal cells would withstand slow freezing in this medium, but not in Ringer alone. It appears that slow freezing of skin grafts is, from all considerations, preferable to fast. B. J. Luyet, however, claimed that his results on the survival after freezing of muscle fibres, chick embryo amniotic muscle and heart, red blood cells, 'vinegar eels', frog spermatozoa, moss leaves and the epidermal cells of some plants confirm in general the predictions of the theory of vitrification by *rapid* cooling, especially with regard to (*a*) the necessity for a high freezing velocity together with subsequent rapid re-warming, (*b*) the beneficial effect of an initial reduction in water content, (*c*) the existence of a limited range of 'dangerous' temperatures, and (*d*) the innocuity of very low temperatures once they have been attained. He described techniques for the determination of cooling velocities which are capable of measuring speeds as high as 3×10^5 deg. C. per sec., and for obtaining such high velocities. R. D. Passey, L. Dmochowski and I. Lasnitzki discussed the freeze-drying of mouse tumours and the assessment of cell survival by growth of the rehydrated tissues in tissue culture or by grafting into susceptible mice. They stressed the need for reliable, non-destructive methods for the estimation of residual water in the dried tissue.

In the last paper of this session, A. S. Parkes gave the results obtained by himself and his collaborators (Miss A. U. Smith, C. Polge and H. A. Sloviter) on the survival after freezing of spermatozoa, endocrine tissue and red blood cells. Both fowl semen and bull and goat sperm withstood freezing in bulk to −79° C. in Ringer–glycerol and resumed full motility on thawing. Slow removal by dialysis of the glycerol from thawed fowl semen gave a sperm suspension with normal fertilizing power. The cumulus cells of rabbit ova grew in tissue culture after rapid (or slow) freezing of the ova in solid carbon dioxide or liquid air. Fragments of adult ovarian tissue similarly treated retained, after implantation, their endocrinological activity but the ova were destroyed. The freezing at −79° C. of whole rabbit or guinea pig blood diluted to a final concentration of 10–15 per cent glycerol was followed by recovery on thawing—even after three months of storage—and the glycerol could be removed by dialysis. The long-term storage of rare types of whole human blood and even of endocrinological 'spares' thus seems to be practicable.

The third session, with Dr. C. H. Andrewes in the chair, brought together papers on the freeze-drying of bacteria and viruses. R. M. Fry has found that suspending media for the drying of bacteria are improved by the addition of 5–10 per cent glucose or lactose, which he considers probably prevents the culture from being over-dried. In addition, a protective colloid is necessary for optimum results, and broth, serum, albumin, hæmoglobin or milk have been used. For especially delicate organisms such as *N. gonorrhœæ* and *V. choleræ* a mixture of one part nutrient broth and three parts human serum, and containing 7·5 per cent glucose, gives optimum results. Similar conclusions have been reached by H. Proom from his experience in the preservation of more than 2,500 bacterial strains. A drying temperature lower than −30° C. is found to be essential and, so far as storage loss is concerned, two factors are important, namely, residual water content and the presence or absence of oxygen. It is therefore recommended that cultures should be given a secondary drying, sealed in dry, oxygen-free nitrogen or *in vacuo* and stored at the lowest practicable temperature.

R. Daubney described the units at Abbassia, Cairo, for the production of vaccines for veterinary use. Rinderpest vaccine, which freeze-drying has made available at very low cost, has, in a few years, given life-long protection to millions of native cattle of such low economic value that they did not warrant the expense of immunization by older methods. Dr. Daubney discussed the factors of preparation—desiccation, including the rate of application of heat to the drying product; residual moisture and temperature of storage of the dried product—all of which determine to a more-or-less extent the overall loss in viability of the ultimate product.

I. A. Galloway, L. H. Collier and Wilson Smith contributed papers on problems they have encountered in drying viruses, vaccines and anti-sera, and

S. T. Cowan dealt with two aspects of infection in drying procedures: cross-infection in the vacuum chamber where different organisms are being dried at the same time, and human infection as a result of aerial contamination of the room in which ampoules are being filled or of lack of care in handling and opening dried cultures.

The final session, with Prof. J. F. Danielli in the chair, comprised four papers on tissue fixation by freezing and drying. I. Gersh stressed the importance of techniques which would preserve cell structure for specific purposes in a state which approximated as closely as possible to that which is obtained in the living state, and gave an example in the use of polyethylene glycol in the infiltration of dried tissues, such as adrenal, for the excellent preservation of lipids. The calculations of J. L. Stephenson have shown that the limiting factor in the speed of withdrawal of water from frozen tissues is not the size or design of the vacuum system but the resistance of the dry tissue mass to the passage of further water vapour.

The papers and illustrations of B. Sylven, of F. Sjöstrand and of L. G. Bell show, beyond doubt, that the disadvantages such as dissolution of cell contents, diffusion within the cell, chemical reaction and physical change of common fixing procedures can largely be avoided by freeze-drying. However, the cell proteins might still be denatured, and it is also most important both that the existence of ice-crystal artefacts should be recognized, and that subsequent cytochemical operations upon dried material should be carefully controlled.

Various aspects of the techniques were discussed, and the meetings may be considered to have served their purpose if, in the opening words of Dr. Greaves, "in the pooling of our ideas . . . our knowledge of this most useful technique may be advanced". The full proceedings of the symposium will be published by the Institute of Biology (Tavistock House South, Tavistock Square, London, W.C.1).

R. J. C. Harris

DRY OXIDATION AND WET CORROSION[*]

By Dr. U. R. EVANS, F.R.S.

Department of Metallurgy, University of Cambridge

TWENTY-FIVE years ago it was customary to draw a sharp contrast between high-temperature oxidation (then regarded as a simple example of direct combination between metal and non-metal) and wet corrosion at low temperature (a complex electrochemical phenomenon). The fact that the alloying constituents—chromium, aluminium and silicon—added to combat the first trouble often serve to prevent the second suggests that the two phenomena are not wholly disconnected. An attempt is made in this article to present an interpretation which covers them both.

High-temperature Oxidation. Metal heated in air becomes covered with an oxide film, which increases in thickness, rapidly at first, but then more slowly. The fact that the film continues to thicken at all indicates that either oxygen must cross it (moving inwards) or metal must cross it (moving outwards). It is now known that metal moves outward as cations and electrons; the electrons arriving at the outer surface convert any adsorbed oxygen atoms into ions, while the metallic cations take their place between them, giving an additional layer of oxide. Thus new oxide is built up continuously on the *outside* of the oxide-film. This outward movement of metal is met with also in the case of sulphide films and is responsible for the curious fact, recorded by Fischbeck and Dorner[1], that a copper wire exposed to liquid sulphur gives a *hollow tube* of sulphide.

Much evidence for outward movement was provided by Pfeil[2], while Wagner[3] and Mott[4] have put the matter on a quantitative footing. The oxidation-rate depends on the *electrical* properties of the *oxide*, and where these are known the oxidation-rate, calculated from electrical data, agrees well with that measured directly; the comparisons between calculated and measured values of film-growth provided by Wagner[3] include films not only of oxide but also of sulphide, bromide and iodide. Evidently, any film which resists the passage *either* of cations *or* of electrons should be protective; that is probably the cause of the protective quality of oxide films containing chromium, aluminium and silicon, and explains why, when these elements are added to iron and other metals, they confer resistance to high-temperature oxidation.

Oxygen in Wet Corrosion. The corrosion-velocity of metal immersed in water is connected with rate of replenishment of oxygen at the metallic surface and can be altered by moving the metal more quickly through the liquid or, under stagnant conditions, by increasing the oxygen-pressure in the gas mixture above the liquid. In general, the corrosion-velocity first increases with the rate of oxygen-replenishment, reaches a maximum and then decreases. For iron or zinc in neutral or weakly acid liquids, the maximum occurs at a high replenishment-rate, and under ordinary conditions oxygen is a 'stimulator' of corrosion. In alkaline liquids, the maximum occurs at a lower replenishment-rate[5] and oxygen can sometimes be regarded as an 'inhibitor'. Also, certain other inhibitors are only effective in presence of oxygen; the chalky protective film, which allows some hard waters to be run through steel pipes without bad results, is only satisfactorily produced in the presence of oxygen; Haase[6] states that organic reducing-agents interfere with its formation and should be destroyed with hypochlorous acid. For stainless steel[7] and aluminium[8], oxygen often reduces the corrosion-velocity—even in acid solutions.

When pure iron[9] or zinc[10] is whirled rapidly in pure distilled water containing oxygen, it undergoes no appreciable change and no visible corrosion-product appears in the liquid; placed in the same water containing the same oxygen under stagnant condition, iron soon develops rusty spots and zinc develops white spots, below which pits are found. Under whirling conditions the rate of replenishment of oxygen is high, permitting an invisible oxide-film to be formed by the outward movement of cations and electrons indicated above; the rate of thickening becomes extremely slow at a very low value of the thickness—the film being still invisible. (The film formed on unheated metal exposed to dry air is also invisible; the oxidation, which can be detected gravimetrically, electrometrically or optically, probably occurs mainly at sensitive spots—a term explained below—and soon becomes extremely slow.)

---

[*] Substance of a lecture delivered at a joint meeting of the Chemical Society (London) and the University of Birmingham Chemical Society, held in the Chemical Lecture Theatre, University of Birmingham, on October 26.

If, however, zinc is immersed in stagnant water, the replenishment-rate of oxygen becomes low; there is now a risk that at 'sensitive' spots cations may arrive at the external surface more quickly than oxygen arrives and can then escape into the liquid as hydrated ions, so that local corrosion, leading to pitting, occurs; a sensitive spot may be a place where the film is thin or cracked or rich in lattice defects, or a point where, owing to local strain in the metal, there is an abnormally high supply of high-energy cations which can move outwards more quickly than they can be 'arrested' by the oxygen. If the material is stainless steel or aluminium, and builds a highly protective film-substance, a much slower replenishment-rate suffices to ensure the arrest of the outward-moving cations, and it is not necessary to 'whirl' the specimens in order to avoid corrosion; nevertheless, oxygen is needed, and some liquids, which do not normally attack stainless steel or aluminium, produce corrosion if all the oxygen is eliminated. We see why those elements (for example, aluminium, chromium and silicon) which confer resistance to high-temperature oxidation, often confer resistance to low-temperature wet corrosion, and also why corrosion sometimes starts at crevices inaccessible to oxygen.

Electrochemical Mechanism. If on zinc or iron placed in a dilute salt solution the oxygen replenishment is insufficient to arrest the emerging cations at a sensitive spot, they will emerge into the liquid as hydrated ions (unless the liquid contains an anion forming a nearly insoluble salt, or a substance which prevents emergence in some other way). However, the emergence of cations must leave an excess of electrons in the metal, and the negative charge would halt the process unless the electrons were used up in reducing oxygen, either to hydrogen peroxide or to hydroxyl. A rate of oxygen-replenishment which is insufficient to arrest the cations emerging at the sensitive spot may nevertheless serve to use up the electrons left in the metal, since this can occur anywhere on a relatively large area around the sensitive spot. The two reactions can proceed without hindrance—the 'anodic reaction' (the passage of cations into the liquid at the sensitive spot), and the 'cathodic reaction' (the reduction of oxygen at the area around it); the migration of anions and cations through the liquid towards the anodic and cathodic areas prevents accumulation of charge anywhere.

Thus we have arrived—by an unfamiliar argument—at the well-accepted electrochemical mechanism of corrosion. The idea that the 'film theory' and the 'electrochemical theory' are rivals is clearly wrong; each expresses the same essential idea—approached from a different angle. It may be doubted, however, whether the word 'theory' should be applied to the electrochemical mechanism, which is to-day established on a firm experimental basis; the currents passing between cathodic and anodic areas have been measured by six independent experimental methods and been found equivalent to the corrosion-velocity measured chemically or gravimetrically.

Inhibitors. With iron in saline water (say, a dilute sodium chloride solution), very rapid whirling is needed before oxygen can act as an inhibitor[11]. Normally, oxygen helps the corrosion both of iron or zinc, since the corrosion products (iron or zinc chloride at the anodes, and sodium hydroxide at the cathodes) are freely soluble, and the solid oxides or hydroxides (rust in the case of iron) are only precipitated where they meet at a perceptible distance from the corrosion site. But if sodium phosphate or sodium hydroxide is present, a supply of oxygen otherwise insufficient may now suffice to stop attack, since any cations which are not arrested by the oxygen can be arrested by the phosphate or hydroxyl ions. Thus Mayne and Menter[12] have found, by electron diffraction, that the invisible protective film formed on iron placed in sodium orthophosphate solution containing oxygen consists partly of gamma-ferric oxide and partly of hydrated ferric phosphate. Likewise, Pryor and Cohen[13] have shown that, in the *p*H-range between 7·2 and 10·0, phosphates completely prevent corrosion in the presence of oxygen but fail to prevent it if oxygen is absent. The amount of phosphate—or other inhibitor—has to be increased if chlorides are present.

Corrosion by aqueous solutions is complicated by the fact that these always contain hydroxyl ions which may serve to arrest emergent cations under some conditions, since the hydroxides of most heavy metals are sparingly soluble. As to whether a solution of sodium chloride (or sulphate) will attack a metal, producing its soluble chloride (or sulphate), or build a protective layer of hydroxide (or oxide), depends largely on the *p*H value, which may itself be changed by the incipient reactions. The principles involved are discussed elsewhere[14]. Evidently, although there are analogies between high-temperature oxidation and wet corrosion, there are also differences.

Effect of Sulphur. It has been shown why certain alloying additions (chromium, aluminium and silicon) which retard high-temperature oxygen often prevent low-temperature wet corrosion. The same reasoning shows why certain other elements, particularly sulphur, enhance both types of attack. Copper, like most other metals, suffers no visible change if exposed to pure air at ordinary temperatures; a film is formed, but its rate of thickening becomes very slow while it is still invisible[15]. However, copper exposed to air containing a trace of hydrogen sulphide gives the same sequence of interference tints as is obtained in pure air at a slightly raised temperature[16,17]. The presence of foreign (sulphur) atoms in the oxide film favours the lattice defects and allows more rapid passage outwards, so that 'visible' thicknesses are reached at ordinary temperatures; other sulphur compounds present in town air enhance atmospheric attack. Sulphur plays a similar part in promoting wet corrosion. A polished iron specimen placed in a solution containing sodium chloride with sufficient inhibitor (sodium carbonate) to prevent corrosion over the greater part of the surface is nevertheless attacked locally around sulphide particles; inclusions of silicate and alumina do not act as sensitive spots[18]. The phenomenon is not shown by coarsely abraded iron, since the deformed material then provides sensitive spots which mask the effect of the sulphide inclusions.

Effect of Impurities. Atoms of a foreign metal can greatly reduce the protective character of an alumina film. A copper–aluminium alloy, if first heated under very feebly oxidizing conditions to produce an alumina film free from copper, shows far greater resistance when afterwards heated in oxygen than the alloy which is exposed to the strongly oxidizing conditions from the first—since, then, the film consists of alumina with copper oxide in solid solution[19]. Similarly, commercial aluminium containing iron and other impurities is much more attacked by citric acid containing sodium chloride than pure aluminium, which forms a highly protective film; in the latter case the attack is localized[8] and may take the form of pitting, so that purity is not always an advantage.

It should be added, however, that this is not the only reason why impure metals are sometimes corroded more quickly than pure metals. Commercial zinc is attacked more rapidly by acids than pure zinc because the metallic impurities, passing into solution, are reprecipitated to form cathodes of low 'overpotential', on which hydrogen can readily be liberated.

OBITUARIES

Dr. Harald Blegvad

The science of marine biology has suffered a great loss by the death on August 22 of the director of the Danish Biological Station, Dr. Harald Blegvad. Blegvad was born on the small Danish island, Samsø, on July 24, 1886. When he had matriculated at the University of Copenhagen in 1904, he took up the study of natural history; he took the degree of M.Sc. in 1910 and in 1921 he obtained a doctorate for a thesis on the biology of some coastal Gammarids and Mysids.

Already as a student he took part in cruises with Danish research vessels in home waters and in the Atlantic. In 1908 he became assistant at the Danish Biological Station, and in 1931 he succeeded A. C. Johansen as director of the Station.

Blegvad's scientific work centred upon the study of the biology of the marketable fishes and of their food organisms. The long series of papers from his hand bear evidence to his keen eye for the essential points of the problems, and further of his clear understanding of what conclusions the material available allowed. His papers show that he possessed that sober self-criticism which is so indispensable to all true scientific work.

Blegvad combined science and practice, and his services to the fishery industry were manifold. He worked on the transplantations of plaice and cod, on the protection of fishes, and, on trips with fishing vessels, he tried new gear and helped the fishermen to find new fishing grounds. Through his personal contact with fishermen and by publishing popular articles and handbooks, he caused a growing understanding of the value of biological science to the fishery industry.

In the work of the International Council for the Exploration of the Sea, Blegvad played a great part; during 1931–45 he was chairman of the Transition Area Committee and since 1945 he had been general secretary to the Council.

As a result of his international reputation as a fishery expert, Blegvad was often called upon by foreign governments which wished to re-organize their fisheries. In 1928 he acted as fishery expert in Lithuania, during 1936–38 he was for two half-years in Persia, and in 1949 he worked for the Government of Ceylon.

By his friends and colleagues Blegvad was much appreciated for his fine, human qualities. He was kind, true and helpful, and his sudden death by heart-failure caused widespread regret.

Erik M. Poulsen

Dr. E. G. V. Percival

The death of Dr. E. G. V. Percival at Edinburgh on September 27, at the early age of forty-three, at the height of his powers as a teacher and investigator, is a serious loss to organic chemistry.

Edmund George Vincent Percival was born at Coalville in 1907 and was educated at King Edward VII Grammar School, Coalville, and at the University of Birmingham. After a brilliant undergraduate career he joined Dr. (now Prof.) W. Wardlaw in researches in inorganic chemistry. This experience was followed by a period with Prof. Harold Hibbert at McGill University, Montreal, where he undertook physico-chemical investigations in the field of cellulose chemistry.

With this wide background Percival returned to Birmingham as research fellow in Sir Norman Haworth's laboratories, where he speedily acquired the interest in carbohydrate chemistry which he maintained so vigorously to the end of his life. In 1933 he was appointed lecturer in chemistry in the University of Edinburgh, and was promoted to a readership in 1948. He was a member of the Faculty of Science, a director of studies and in 1951 he was elected a member of the Senatus Academicus. In addition to his University work, Percival gave generously of his services to the Royal Institute of Chemistry, the fellowship of which he had gained in 1936, and to the Society of Chemical Industry. He became a fellow of the Royal Society of Edinburgh in 1938. For many years he took an active interest in the work of the Pharmaceutical Society and of the Scottish Seaweed Research Association. In 1948, when the annual meeting of the Society of Chemical Industry was held in Edinburgh, and again in 1951 on the occasion of the meeting of the British Association, he played a notable part in securing the success of the local arrangements. He served with distinction on many committees, and at the time of his death he was a member of Council of the Chemical Society.

His interests were wide, including travel, gardening, tennis and cricket. He was an inspiring teacher and director of research, fertile in ideas and energetic in their development. In all his dealings he was supremely generous, and his kindness, understanding and loyalty endeared him to his many friends and colleagues.

Percival was the author of some seventy papers, dealing with the chemistry of the sugars. Among his achievements special mention may be made of his part in the elucidation of the structure of vitamin C, his work on the ring structure of osazones, on the alkali addition compounds of the sugars, on the molecular structure of plant seed mucilages, seaweed polysaccharides (notably agar, fucoidin and laminarin) and the naturally occurring fructosans. In all these subjects he had become a recognized authority, and his book (1950) on the "Structural Chemistry of the Carbohydrates" is a model of its kind.

In 1934 he married E. Elizabeth Kempson, herself a chemist who has collaborated in many of these investigations. She and their two children survive him.

E. L. Hirst

We regret to announce the following deaths:

Prof. R. B. Denison, formerly principal of Natal University College, and president in 1918 of the South African Chemical Institute.

Prof. Allan Ferguson, until 1945 assistant professor of physics in Queen Mary College, University of London, on November 9, aged seventy-one.

Prof. R. Sekiguti, lately director of the Tokyo Observatory, on August 10.

NEWS and VIEWS

Royal Society: Medal Awards for 1951

The following awards of medals have been made by the president and the Council of the Royal Society:

Copley Medal to Prof. D. Keilin, Quick professor of biology and director of the Molteno Institute, University of Cambridge, for his fundamental researches in the fields of protozoology, entomology and the biochemistry of enzymes.

Davy Medal to Sir Eric Rideal, professor of chemistry in King's College, University of London, for his distinguished contributions to the subject of surface chemistry.

Hughes Medal to Prof. H. A. Kramers, professor of theoretical physics in the Technical University, Delft, for his distinguished work on the quantum theory, particularly its application to the optical and magnetic properties of matter.

Physics at Leeds: Dr. J. G. Wilson

Dr. John Graham Wilson, reader in physics in the University of Manchester, has been appointed to the second professorship of physics at Leeds (rendered vacant by the succession of Prof. E. C. Stoner to the Cavendish chair, also at Leeds, on the retirement of Prof. R. Whiddington), and is to take up his new duties in June 1952. Dr. Wilson was born at West Hartlepool, Durham, in 1911, and was educated at the Grammar School there and at Sidney Sussex College, Cambridge. He carried out research for three years at the Cavendish Laboratory, Cambridge, under the direction of C. T. R. Wilson. He then joined P. M. S. Blackett as research assistant at Birkbeck College, London, and was later appointed assistant lecturer in the University of Manchester (1938). During the Second World War he was with the Air Ministry and the Ministry of Aircraft Production.

Dr. Wilson's first research was concerned with the development of new forms of expansion apparatus, which figured largely in his pre-war work on cosmic ray physics. He developed new methods of temperature control which made possible high-precision measurements of momentum above and below an absorbing plate placed in a cloud chamber, and, with Blackett, he made extensive measurements of the energy loss of cosmic ray particles in such plates. Since the War, his immediate work has mainly been in the design, construction and application of the momentum spectrograph for cosmic ray particles which has been built in Manchester. In addition to his papers, Dr. Wilson has written a valuable specialist book, "Principles of Cloud Chamber Technique", and an eminently readable general book, "About Cosmic Rays", and he has edited a volume on "Progress in Cosmic Ray Physics" which is to be published shortly. At Leeds, where most of the research is concerned with the solid state, in its atomic and electronic aspects, Dr. Wilson will greatly strengthen the representation of nuclear physics in the Physics Department. At the same time his keen interest in work with undergraduates will do much to ensure the maintenance of a proper balance between teaching and research.

Veterinary Science in the University of Queensland: Prof. John Francis

It is announced that Mr. John Francis has been appointed to the newly-established chair of preventive medicine within the Veterinary Faculty of the University of Queensland. This is the second professorship to be filled since the full five-year veterinary course was re-established in 1950, the earlier one being in animal husbandry (see *Nature*, 166, 136; 1950). The designation of the two senior research and teaching posts within the young faculty in this manner serves to emphasize the present trend in veterinary science. The aim of reducing economic loss and animal suffering is being met by an increased application of pathological and bacteriological knowledge to the prevention of disease, while recent advances in animal physiology and genetics are being applied to increase the efficiency of animal production. Queensland, with nearly eight million cattle, eighteen million sheep and more pigs than any other State of the Commonwealth, and with the majority of its stock within the tropics, possesses many important unsolved epizootiological and ecological problems. The shortage of veterinarians is acute in every Australian State; but it is believed that the development of the Veterinary School of the University of Queensland will in time greatly help to overcome this.

Mr. Francis graduated from the Royal Veterinary College in 1938, having concurrently taken the B.Sc. degree of the University of London. He was for a year demonstrator in bacteriology at the Royal Veterinary College before becoming a research officer at the Foot and Mouth Research Station, Pirbright. In 1943 he joined the Biological Department of Imperial Chemical Industries, Ltd., and studied the metabolism and antibacterial action of the sulphonamides and sulphones. This work has led to a better understanding of their application in veterinary medicine, and also to the use of 4 : 4′-diamino diphenyl sulphone for the treatment of leprosy; this sulphone is the first effective drug cheap enough to be used on a wide scale. The isolation of the growth-factor for *Myco. johnei*, first demonstrated by Twort and Ingram in 1913, has added to our knowledge of the acid-fast bacteria and may assist in the development of chemotherapeutic substances. In addition to his main work on the application of chemotherapy to veterinary medicine, Mr. Francis has developed a keen interest in many problems of epizootiology. This has been shown in recent years in his studies of bovine tuberculosis and the relationship of the bovine disease to that in man, on which he published a book in 1947. He was a delegate to the World Health Organization conference in Geneva last year, where recommendations were made for the control of 'zoonoses', or animal diseases transmissible to man.

Scientific Workers and Defence Research in the United States

A STATEMENT on scientific workers and mobilization, issued on September 12 by the Science Advisory Committee of the United States Office of Defense Mobilization, makes a number of suggestions regarding the participation of universities or academic men of science in research on defence in America. The Department of Defense has already expanded its research and development to more than double that of the late 1940's, mainly in industry and government laboratories, and only about 10 per cent of it represents work done on contract with universities. The statement expresses the view that the major part of the academic research effort of the United States should, in present circumstances, continue to be devoted to fundamental research, but that there should be an appropriate balance between academic science and the abnormal and immediate demands of military problems. A substantial portion of the academic effort should accordingly be devoted to urgent defence needs and to building up throughout the academic community a widespread knowledge of the scientific problems of defence and a reserve of scientific workers to meet emergencies.

The statement suggests that outstanding men should be made available to projects which analyse military objectives in a broad area of technology and possible means of achieving them, and also to other defence activities where they can simultaneously learn research needs by participating in them. Specially qualified leaders should be given leave of absence to take positions in the Department of Defense and other government agencies which will familiarize them with the problems needing attention. Universities and colleges, it is suggested, should welcome opportunities for joint projects. To a considerable extent the best place for an individual scientific worker depends on whether his own interest and aptitude are for fundamental research and teaching or for applied research or administrative work on defence projects. Periods of leave for such defence work should be of specified duration, both to prevent undue interruption of an individual's normal activities and to spread participation in defence research. The importance to the United States of research and teaching is a major consideration. With these conditions the Committee believes that research and teaching activities would also benefit by widening the experience of scientific workers. The signatories to the statement include the chairman, Dr. Oliver E. Buckley, and Dr. D. W. Bronk, Dr. L. Dubridge, Dr. J. R. Killian, Dr. R. F. Loeb, Dr. J. B. Conant, Dr. J. R. Oppenheimer, Dr. C. A. Thomas, Dr. A. Waterman, Dr. H. Dryden and Dr. W. Whitman.

French Palæontological Documentation and Translation Service

THE Centre d'Études et de Documentation Paléontologiques, Muséum d'Histoire Naturelle, Paris, was set up in 1947 with the aim of providing the palæontological documentation required by the modern research worker in the different branches of the sciences of the earth. In addition to supplying general bibliographical information, the Centre has developed its translation service and provides, for scientific workers in France and elsewhere, French translations of recent publications in other languages, in particular, in Dutch, German, Polish and Russian. It has concentrated on the two types of translation: articles on subjects which are of particular interest at the present time, such as tectonics (and in particular neotectonics), sedimentation, the Quaternary era and evolution; and, within the field of palæontology, translation of works on systematics, especially of those written in Russian, in order that descriptions of new forms should be readily available. So far, nearly four hundred translations have been made, 80 per cent of them being of Russian, Polish or Dutch works. The three-monthly bulletin published by the Centre gives the titles of the new translations as they are prepared, and complete lists of all the translations made since the Centre was set up can also be obtained. At the request of other organizations or research workers, the Centre also carries out special translations, and these and the diagrams can be easily reproduced. The charges for reproductions of translations are approximately 10*d*. per page of text, plus 2*d*.–1*s*. each for photostats of the diagrams, depending on the size. Further information can be obtained from J. Roger, Centre d'Études et de Documentation Paléontologiques, 3 Place Valhubert, Paris 5e.

Preparation of Manuscript for Publication

UNDER the title "Preparing Technical Material for Publication; a Manual for Authors of College and Station Publications", the University of Illinois Engineering Experiment Station has issued as Circular Series No. 62 (pp. 39; Urbana: University of Illinois, 1951; 60 cents) a revised and enlarged edition of the manual "Preparation of Manuscript" published by the Station fifteen years ago. It deals especially with the publications issued by the Experiment Station and by the College of Engineering, alone or in collaboration with other divisions of the University, including recommendations for the preparation of manuscript and illustrations and also for proof-reading. Much of the material, particularly in the first three chapters relating to the range and form of publications issued by the Station and College, is concerned with the characteristic style or form of those publications; but the succeeding chapters, dealing with content and preparation of copy, contain comments and observations of general validity. While much of this is thoroughly sound, there is little to justify commending the manual to British, as distinct from American, writers, particularly in view of the recent flow of British publications of this type, among which it should suffice to mention the "General Notes on the Preparation of Scientific Papers" issued last year by the Royal Society and which itself gives a representative list of British reference books. The bibliography included in the Illinois manual is entirely American and, even so, omits two of the best American books: S. F. Trelease's "The Scientific Paper" and J. R. Nelson's "Writing the Technical Report". There is a further reason for caution in recommending this manual to British readers. While the principles of arrangement and construction are independent of language, when it comes to the handling of words, the fact that the manual is written in English can disguise the truth that British and American writers are really dealing with two different languages. The same words quite commonly have different meanings or nuances. This is apt to give the impression, which sometimes may be quite mistaken, that American writers do not handle their tools with the same precision or show the same regard for style as their British confrères.

Physical Society: Meeting at Southampton

The autumn provincial meeting of the Physical Society will be held in the Physics Department of University College, Southampton, during December 18–19. The meeting will be divided into three sessions on the following subjects under the direction of the persons indicated: (1) optics of metals (Prof. A. M. Taylor); (2) thermal properties and growth of crystals (Mr. S. Weintroub); and (3) complex spectra and nuclear structure (Prof. H. A. Jahn). In addition to contributions from the Departments of Mathematics and Physics of University College, Southampton, papers will be presented by members of the Physics Departments of the Universities of Birmingham, Bristol, London (Royal Holloway College and Guy's Hospital), Oxford and Reading, and of the South-West Essex Technical College, Walthamstow, the Atomic Energy Research Establishment, the Telecommunications Research Establishment, the British Scientific Instrument Research Association, and Hilger and Watts, Ltd. The meeting is open to non-members of the Society. Application forms and further information can be obtained from the Secretary-Editor of the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

Awards for Technical Writing on Radio

To encourage the writing and publication of articles reporting technical progress and development in radio and electronics in Great Britain, the Radio Industry Council is to award premiums of twenty-five guineas each, up to an average of six a year, to the writers of published articles which, in the opinion of a panel of judges, deserve to be commended by the industry. It is hoped in this way gradually to increase the number and standard of articles available to editors. Any non-professional writer will be eligible, and the awards will be made for articles published in Great Britain or abroad in papers or periodicals which can be bought by the public on the bookstalls or by subscription. Writers and editors will be invited to submit published articles to the Secretary, Radio Industry Council, 59 Russell Square, London, W.C.1 (if possible, five copies of the journal, proofs or reprints), for consideration. The judges will be asked broadly to take into consideration the value of an article in making known British achievement in radio and electronics, originality of subject, technical interest and presentation and clarity. The judges will be four members of the Radio Industry Council, and Prof. Willis Jackson, professor of electrical engineering, Imperial College of Science and Technology, University of London, assisted by the editors of *Wireless World* and *Electronic Engineering*.

Gas Council Research Committee

Additions to the membership of the Gas Council Research Committee have been appointed as follows: J. H. Dyde, president of the Institution of Gas Engineers; G. le B. Diamond, chairman of the West Midlands Gas Board; Prof. F. H. Garner, professor of chemical engineering, University of Birmingham, and part-time member of the West Midlands Gas Board; and Dr. F. J. Dent, director of the Gas Council Birmingham Research Station. The Committee was established in September of last year with the responsibility of advising the Gas Council on all matters connected with research, drawing up programmes and reviewing progress from time to time.

Announcements

The American Society for the Study of Sterility is offering a prize, with a cash award of 1,000 dollars, for the most outstanding contribution to the subject of infertility and sterility, as judged from among essays submitted for this competition, which must be received not later than March 1, 1952. Further particulars can be obtained from the Society at 20 Magnolia Terrace, Springfield, Massachusetts.

Applications for grants from the Clough Memorial Research Fund of the Edinburgh Geological Society are invited for the period April 1, 1952–March 31, 1953. This Fund was instituted in 1935 for the purpose of encouraging geological research in Scotland and the North of England, the latter being defined as comprising the counties of Northumberland, Durham, Cumberland, Westmorland and Yorkshire. Applications must be in the hands of the Secretary, Clough Memorial Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh, 1, not later than March 1, 1952.

The Institution of Naval Architects has made the following awards: 1851 Exhibition Commissioners Postgraduate Research Scholarship in Naval Architecture (1949), of £500 a year, to I. M. Yuille, for one further year; Sir William White Postgraduate Scholarship in Naval Architecture (1951), of £150 a year for two years, to M. C. Eames, of King's College, Newcastle upon Tyne; Aluminium Development Association Research Scholarship in the Application of Light Alloys to Ship Construction (1949), of £400 a year, to J. B. Caldwell for one further year; Elgar Scholarship in Naval Architecture (1951), of £175 a year for four years at the University of Glasgow, to R. R. Phillips, of H.M. Dockyard, Devonport; Vickers-Armstrongs Scholarship in Naval Architecture (1951), of £220 a year for three years at King's College, Newcastle upon Tyne, to G. A. Smith, of Aldous Successors, Brightlingsea.

PRE-BREAKDOWN DISCHARGES IN D.C. POSITIVE POINT TO PLANE CORONA

By H. M. GAUNT and DR. J. D. CRAGGS
Department of Electrical Engineering, University of Liverpool

PREVIOUS workers[1-4] have shown that D.C. positive point to plane corona in air and in other gases of moderate purity consists of several forms of discharge. These are, in order of appearance with increasing voltage, burst pulses and pre-onset streamers, burst corona and finally streamers the lengths of which increase with voltage until one of them crosses the gap and gives rise to a spark.

Recently it has become apparent that a further discharge is present in conditions suitable for streamer formation. In D.C. coronas, this discharge is of a filamentary nature, and, it is submitted, should be clearly distinguished from streamer discharges. It will be referred to in this article as the 'filamentary' or 'diffuse discharge'.

Discharges have been found in impulse corona, mainly by Saxe[5,6], Komelkov[7,8] and others[9-11] which differ from the classical streamers[1-4,12]. Confusions in nomenclature have arisen; but in the present discussion a streamer is taken to be a filamentary discharge which, on crossing the discharge gap, leads to a breakdown.

Discharges in air. A photograph of pre-breakdown corona in air, taken with a small aperture and long exposure, is shown in Fig. 1. Three distinct regions are visible: (*a*) a very intense glow, localized at the point surface; (*b*) an intense discharge directed outwards from the point in a straight line along the axis of the gap with a fairly sharp termination; and (*c*) a fainter continuation of zone *b* which spreads out into a diffuse luminous cone; only the more intense part of the latter discharge is visible in Fig. 1 because of the small aperture used. (*a*) is probably a region in which a succession of avalanches moves into the point, as in burst corona; (*b*) is the region of the pre-breakdown streamers which are limited in extent to the high-field region around the point; and (*c*) shows the diffuse discharges which have a filamentary structure.

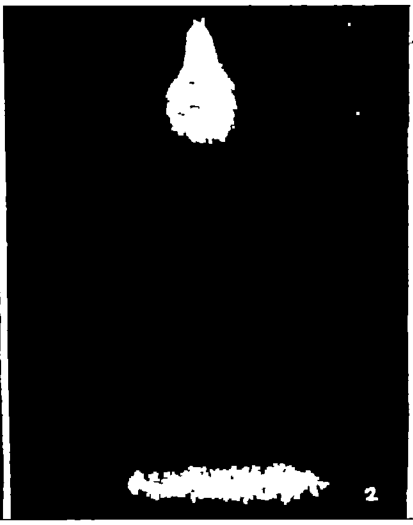
The electrode geometry has little effect on the discharge.

The filamentary discharge (*c* above) has been studied with a photomultiplier – video amplifier – oscillograph technique. Light pulses from two small regions of the discharge, one near the streamers and one near the plane, have been displayed on the oscillograph screen so that, knowing the distance apart of the two observed regions and the time displacement of the pulses observed on the screen, the velocity of propagation of the filamentary discharges towards the plane could be measured. The mean velocity across the gap was thus found to be $\sim 10^7$ cm./sec., which is of the same order as the lower published values for streamer velocities.

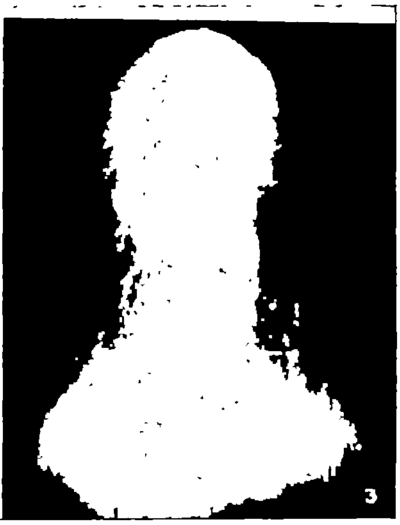
A further experiment was carried out to test for simultaneity of the streamers and the filamentary discharge. A photomultiplier tube and amplifier were used for displaying light pulses from the streamers on one beam of a double-beam oscilloscope, while another photomultiplier and amplifier displayed light pulses from the filamentary discharge on the other beam. The coincidences of the pulses showed that the streamers and the filamentary discharge occurred more or less simultaneously.

Light pulses from two separate parts of the filamentary discharge, situated on opposite sides of the axis, were recorded with the above apparatus. Simultaneous pulses showed that many filaments are propagated at once. These experiments suggest that the discharge consists of an intense streamer extending

1



2



3

Fig.	Gas	Gap length (cm.)	Point diam. (mm.)	Camera exposure	Voltage of fig. (kV.)	Sparking voltage (kV.)
1	Air	5·6	1·5	60 sec. : *f*/6·3	34	37
2	Nitrogen	7	0·2	2 sec. : *f*/1·5	36·5	37
3	Argon	5·8	0·2	5 sec. : *f*/1·5	—	—

a few millimetres from the point with many less intense filaments being propagated from the streamer to the plane, with a possible continuous luminous background. The whole discharge occurs in about a microsecond, repeating every few hundred microseconds.

If the voltage drop along the streamer is negligible, the applied voltage will appear across the filamentary discharge. In typical conditions, some 30 kV. is thus applied to filaments about 5 cm. long so that the mean potential gradient is roughly 6 kV./cm., to be compared with Komelkov's figure[8] of 6–8 kV./cm.

Discharges in nitrogen. The appearance of the corona discharge near spark breakdown in nitrogen differs greatly from that in air. The streamers in nitrogen are much longer and more erratic than in air and are often branched at their extremities (Fig. 2). In nitrogen of commercial purity, the filaments in the filamentary discharge are apparently fewer and less diffuse than in air; there is also a large increase in intensity of the filaments very near the plane (Fig. 2), although occasionally this increased intensity occurs along about 3–4 mm. of filament.

The addition of a few per cent of air shortened the streamers and tended to concentrate them along the axis. Ultimately, as the proportion of air increased the discharge tended gradually to that observed with air.

Discharges in argon. The corona in argon resembled that in nitrogen, showing long erratic streamers, in general agreement with Weissler[4]. The filaments were intense in regions very near the surface of the plane electrode (Fig. 3).

The effect of adding air was less than might be expected from Weissler's results[4], since several per cent of this contaminant merely produced a slight rise in starting voltage and little alteration in the appearance of the discharge.

Discharges in oxygen. The corona in oxygen was very faint, as in hydrogen, even though the applied voltage was about 65 kV. compared with 30 kV. in the other gases. Streamers were visible before breakdown, extending a few millimetres from the point as in air. The filamentary discharge was invisible except for a faint glow near the tips of the streamers and a glow near the plane electrode which was so faint that it was scarcely visible.

Discussion. If the discharges referred to above as 'streamers' are those of the Loeb–Meek–Raether theory, as seems likely since the filaments bridge the gap without causing spark breakdown, then it is desirable to seek a mechanism for the filaments. This point will be discussed later; but for the moment it will be assumed that the streamer theory is not applicable to the filamentary discharge. At present it does not seem possible to formulate a definite mechanism, and this discussion will be concerned with certain suggestions and general tentative conclusions.

The filamentary structure of the discharge, its high velocity of propagation, and the direction of propagation of the filaments all suggest a streamer type of mechanism. The tendency to follow lines of force, the lack of spark breakdown when the filaments bridge the gap, the low intensity and, possibly, the high axial potential gradients suggest that the filaments have lower ion densities than streamers, resulting in less field distortion.

The increased luminosity near the plane can be readily explained if the discharge does, in fact, consist of continuous conducting filaments, since the field between the tip of a filament and the plane cathode will be high when the distance between them is small. This field intensity may be high enough to permit true streamers to be formed near the plane, or may merely increase the intensity of the filaments. Photoemission from the plane probably contributes. It also seems possible that the enhanced intensity is due to a negative leader[10,11] developing from the cathode.

It is known[12–15] that there exists, in certain gaseous discharges, photons which are absorbed less readily than those usually considered to be involved in streamer propagation[13]. Any such photons produced by a streamer will probably cause weak ionization at appreciable distances from the streamer tip. Any photoelectrons so produced will move slowly towards the point, and such of these photoelectrons as find themselves near the tip of the filament may create avalanches which feed into the filaments. It seems possible that it is these avalanches, initiated by the streamer or burst corona, that enable the filaments to be propagated in low fields.

Loeb[14] discusses this discharge in pre-onset D.C. corona, but does not refer to its filamentary structure; and indeed it would be very difficult to observe such a structure in the small pre-onset discharges. He suggests that the discharge is caused by photon absorption some distance from the main streamer channel, and that the photoelectrons so produced move towards the streamer channel along the lines of force, ionizing and exciting atoms in their path. This would give rise to an extended diffuse glow and is inconsistent with many properties of the discharge.

In impulse corona, Saxe and Meek[5,6] have also suggested that the discharge consists of a zone of continuous ionization. Their photomultiplier technique could not by itself reveal the filamentary structure which is apparent in photographic work by Allibone and Meek[16], Garfitt and Meek[17] and others[7,8,11,18].

Other authors[7,8,18] apparently consider that the theory of streamer propagation[13] applies to the filaments and that the breakdown streamer (or leader stroke) is, in some way, formed from these filaments. If this view be accepted, it becomes difficult to account for the absence of a spark when the filaments bridge the gap, which they do at voltages considerably below the sparking potential.

Conclusions. It is now fairly well established that there exists a filamentary but extensive discharge apparently associated with the streamer discharge in inhomogeneous field breakdown.

Since the above work was completed, more than a year ago, new data on breakdown processes in uniform field gaps at high pressures (some hundreds of millimetres of mercury) have been obtained by Fisher and Bederson[19,20] and by Llewellyn Jones and Parker[21]. The former, from a study of formative time-lags at small overvoltages, have suggested that, especially for the rare gases, as described earlier by other authors[22,23], the streamer theory does not apply (at least in its simple form) for low overvoltages, and may be replaced by a Townsend mechanism. For non-uniform field gaps, it is more difficult to explain breakdown by cathode effects, particularly when impulse voltages of short duration are used, although the discharges shown in Figs. 1–3, and notably the argon discharge shown in Fig. 3, show that discharge effects take place at the cathode. The latter authors[21] reject the streamer theory, for uniform field and for point-plane gaps.

Calculations of the field at the plane electrode in point-plane gaps during D.C. corona discharges have been made by Loeb and Meek[24]. Negative-point discharges were studied and it was shown that fields of ∼ 30 kV./cm. or more might be established at the plane electrode.

We wish to thank Prof. J. M. Meek, Mr. W. Hopwood and Dr. R. F. Saxe for many discussions on streamer mechanisms. One of us (H. M. G.) wishes to acknowledge financial support from the Electrical Research Association and also from the Stoke-on-Trent Education Committee.

SUPERPOSITION EFFECTS IN MULTIPLE-BEAM INTERFERENCE FRINGES

By AUDREY M. GLAUERT*

Royal Holloway College, University of London

THE Fizeau fringes given by a pair of flats, placed at a small angle to each other, are straight, lying parallel to the edge of the wedge. If the flats are silvered and the monochromatic illumination is correctly collimated, the fringes are formed by multiple reflexions and are very sharp[1]. If, however, an ordinary thin microscope coverslip is introduced between the flats the appearance of the fringes alters. In the area occupied by the coverslip the fringes are distorted and modulated to a considerable extent (Fig. 1, × 12).

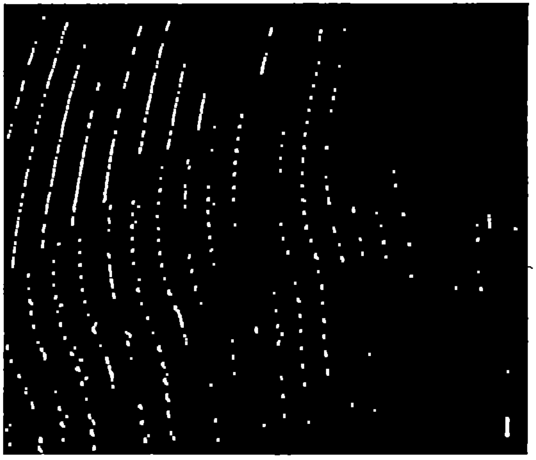

Fig. 1

Corresponding results are obtained if a thin unsilvered slip of mica is placed between the flats: but further unusual effects also occur. Owing to the birefringence of the mica, each fringe is doubled, the light forming the two components being polarized in mutually perpendicular directions. A striking phenomenon is that the two components of a fringe are not modulated in a similar manner in all regions. One component may be practically straight at a place where the other is distorted, while in other parts of the field the effect may be reversed. In some regions both components will appear straight or both curved. This difference in behaviour seems to indicate that the modulation is dependent upon the state of polarization of the interfering light. The effect is illustrated in Fig. 2 (× 15). In (*a*) both sets of fringes are present, whereas in (*b*) and (*c*) a 'Polaroid' has been introduced to exclude one or other of the components. In Fig. 3 (× 12), half the field is covered by the modulated fringes, while the other half shows the 'contour' fringes formed between one side of the mica lamina and the nearest optical flat. The close connexion between the distortions of the wedge fringes and the shape of the contour fringes is clear, and suggests that the modulation effect is due to the superposition of the various fringe systems formed

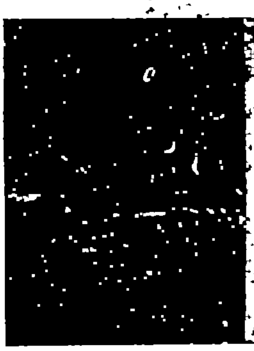

Fig. 3

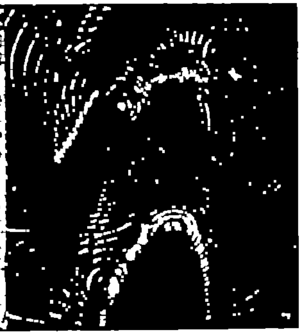

Fig. 4

between the mica and the flats. Finally, in Fig. 4 (× 9), the fringes are shown at high dispersion with the flats lying practically parallel. The right-hand side of the figure shows the contour fringes formed between one silvered side of the mica and the nearest flat, and the left-hand side those between the other silvered side of the mica and the other flat. The central region shows the modulated fringes at high dispersion. In part of the field one component of the fringes remains practically unaffected, while the other is greatly modulated. However, this effect changes considerably as the fringes cross a cleavage step in the mica which can be seen running diagonally across the figure. On the other side of the step the components are equally modulated. This change in behaviour of the modulations on crossing a step was often observed and suggests that the superposition effect is also dependent upon the thickness of the inserted lamina. This is presumably due to the fact that the relative sizes of the relevant air gaps are changed.

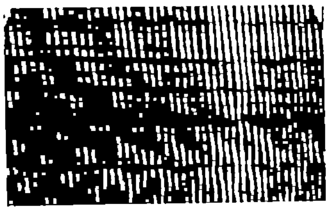

Fig. 5

The corresponding fringes of equal chromatic order[1] were also observed, and an example, obtained with a mica lamina, is given in Fig. 5. Again the fringes are modulated, and it is noticeable that the fringes at different wave-lengths do not have similar shapes. This is unusual for fringes of this type.

The full explanation of the effects described here remains obscure, but as it is no longer possible to continue the investigation it was thought best to communicate the results in their present form. They have importance, particularly with respect to interference experiments carried out to study the structure of biological material. It is often proposed to place a specimen under examination in a suitable fluid between silvered optical flats, in the hope that the resultant fringes will give some indications as to structure and form. The present results show that the greatest care must be taken in the interpretation of such interferograms, and they illustrate the ease of production of artefacts. [June 13.

RACIAL STUDIES

UNESCO's two recent pamphlets, "Race and Psychology" and "The Roots of Prejudice"*, have only their topic in common. Dr. Klineberg's essay is exactly what one would expect from the leading authority on the subject he discusses—a concise statement, rich in usefully selected data, leading to the conclusion that there is "no relation between race and psychology". He admits, of course, that "individuals and families are not equally endowed", and he recognizes the importance of heredity in accounting for differences in mental ability; but he insists that there is "no evidence" for the view that "races or ethnic groups differ in their psychological inheritance. . . . As far as we can judge, the range of capacities and the frequency of occurrence of various levels of inherited ability are about the same in all racial groups."

This is now the prevailing opinion among serious scholars, though an influential minority still rejects it. But, whether one agrees or not, the value of easy access to a factually presented argument for this belief is evident. Students and teachers will certainly find it useful, while those who indulge in racial opinions should at least be discomfited by it.

Dr. Rose's opinionative discourse, on the other hand, is of interest chiefly as an example of the unscientific lengths to which a synthesis embracing recent psychiatric theories, restricted personality studies, uncontrolled speculations and American idealism can be pushed. There are more facts about the nature of prejudice in the records of ancient civilizations, and more about its psychology in Antarah, Ibn Khaldun and Vico, than in the entire body of influencing factors and half-truths sometimes described as "the psychology of race relations"; but Dr. Rose's approach does not include their consideration.

Ibn Khaldun, for example, suggests slavery as a major source of prejudice against Jews and Negroes, and those who know the history of these groups will appreciate his point. Dr. Rose's thinking, however, shapes the astonishing statement that "prejudice was not particularly associated with slavery" in the United States. He prefers the metonymic explanations of the day: "Frustration explains the force behind prejudice. But it does not explain why certain minority groups are chosen as scapegoats. To explain this, psychologists help us out with another theory—the 'symbolic' theory. This theory is based on the important fact that one thing can stand for something else in the unconscious mind."

This process of substitution or symbolization produces unfavourable attitudes against substitutes for "important things in the culture" which engender inadmissible fears, dislikes and rebelliousness. For example, "some people will not admit that they would like to rebel, and these are usually the ones who would most like to do so. They pretend that they adore their parents at all times, that they have 'pure' feelings about sex and religion and so on. Since this is not *really* the case, they have to give vent to their rebel feelings in some way. And they do so by having prejudices against minority groups." Why *certain* minorities are selected, if they are, we are not told, except in terms of fears of large numbers, power and "spying for foreign governments".

---

* (1) "Race and Psychology." By Otto Klineberg. Pp. 39. (2) "The Roots of Prejudice." By Arnold Rose. Pp. 41. (Paris: Unesco, 1951; London: H.M. Stationery Office.) 1s. 6d. each.

It would be carrying criticism too far (perhaps it would be fear of psychiatry) to deny that such explanations represent facets of truth. In fact, the defect of Dr. Rose's propaganda lies not so much in their use as in the manner of their employment: they are out of proportion, without historical pattern, and suffused by a kindergarten brightness that can only be tiresome to adult minds. Moreover, over-anxiety to make a case provokes the very questions he tries to avoid. Thus, when he says that prejudice "has not been universal, in the sense that all cultures or all people have displayed it", the absence of supporting examples tempts disbelief. When he adds that "there is no example of a whole people advancing themselves or their civilization on the basis of it", one is inclined, while making full allowance for the degenerative effects of slavery and xenophobia, to provide him with the examples he has missed.

Another illustration of historical *naïveté* is his classification of intergroup tensions into three distinct types. "One is political in motive" and is "based on a struggle for power"—a popular cliché concealing a complex of economic motivations. The others arise more mysteriously from religious differences and racism, the latter being "largely a modern phenomenon . . . rare until its modern development less than two centuries ago as a perversion of early biological science . . .". Actually, it is an elementary historical fact that all the great religious conflicts have been essentially political, while racism is an ancient phenomenon associated with the structure of the State. Even the new racism goes back to the transformation of mercantile adventures into regular overseas trade towards the end of the sixteenth century; and it has no causative connexion with biology, though it found a rationale in the prevailing (not the perverted) biological thought of the nineteenth century. Therefore, to say that racism is "an independent cause of prejudice today" is to put the cart well before the horse.

Dr. Rose is equally original in other directions. Ignorance, he says, of the costs of prejudice to the prejudiced themselves is a "contributory root" of prejudice, which is a distorted way of saying that such ignorance is a factor assisting the maintenance of prejudice. Nor is his accounting of the financial cost impressive outside the genialities of American business. It is true that prejudice affects man-power efficiency and aggravates social problems, but it is equally true that: (1) no economic system supports situations evidently hostile to itself; (2) the losses caused by the prejudices of a ruling group are slight compared with its gains; and (3) every reduction in prejudice must substantially increase the cost of social reforms. In other words, the appeal to profit is manifestly absurd in a society where the makers of profit know a good deal more about it than Dr. Rose.

To swell the appeal with idle, if unintentionally revealing, speculations is no more than a further invitation to surgery. Perhaps it can be allowed, very doubtfully, that it "is probable that in the long run imperialistic countries could have gained even greater economic advantages if they had not employed prejudice, discrimination and violence"; but in that case they would have ceased to be imperialistic. For no imperial nation has ever been able to maintain its rule without prejudice, and every imperialism has begun to decline the moment it has been compelled to relax its prejudices to the point of admitting selected 'natives' to its own educational resources, culture and social opportunities. A benignly unprejudiced imperialism would be a historical anachronism.

The final judgment on "The Roots of Prejudice" must be that it tells us little about prejudice and less about its roots. It is written by an ideologue, whose excursions in search of originality and moral purpose merely produce over-simplifications that conceal or twist historical truths in accordance with a false empiricism. But Dr. Rose should not be blamed. He is a product, like prejudice, of circumstances, including the complications of academic sterility analysed by Veblen and Robert Lynd.

Unfortunately, the same tolerance cannot reasonably be extended to Unesco. Its policy on intergroup tensions, despite many good results, lacks co-ordinated vision. Consequently, its expensive propaganda is often unscientific, contradictory and confusing—a regrettable situation which is not likely to improve until it is realized that the reduction of "race problems" is beyond the reach of anti-racial journalese. Dr. Klineberg's advantage in providing an instructive exception lies in long personal experience of a subject that has matured; and if Unesco's other humanistic concerns were entrusted to authorities of like stature they would benefit accordingly. Moreover, critical direction would include the promotion of basic studies on those aspects of "the race question in modern science" that are modern enough but not yet scientific. The alternative is to become an advertising agency for dubious scholarship and apparently good intentions.

CEDRIC DOVER

EFFECTS OF DDT UPON DIFFERENT SPECIES OF MOSQUITOES IN MALAYA

By J. A. REID

Institute for Medical Research, Kuala Lumpur, Malaya

THE reactions of *Anopheles maculatus* to DDT in window-trap huts have been shown to be very different from those of *Culex fatigans*[1,2]. With a dose of 200 mgm. DDT per sq. ft. as a wettable powder, it is nearly six months before the mortality of *Anopheles maculatus* drops below 50 per cent. The same dose, even when fresh, scarcely kills any *Culex fatigans*, although for six months it drives them out of the hut into the window-trap, and prevents many from biting.

More recently, experiments with window-trap huts and DDT have been extended to other important Malayan species, vectors of malaria or filariasis. The results during the first six to nine weeks after treatment (see table) indicate a wide range of susceptibility to DDT, as if there is almost a complete reaction spectrum, with very susceptible species such as *A. maculatus* at one end, and the least susceptible such as *Culex fatigans* at the other. The terms 'susceptible' and 'insusceptible' are preferred to 'non-resistant' and 'resistant'. The latter is commonly used to describe strains of house-flies which are not killed by direct application or even injection of DDT. But if a species of mosquito escapes unharmed from a hut treated with DDT, this may be due to

Mortality of Mosquitoes Captured in Window-trap Huts, during Six to Nine Weeks after Treatment with DDT at 200 mgm. per sq. ft. as a 25 per cent Wettable Powder

Species	Control		DDT		Per cent mortality after 24 hr. due to DDT (corrected)
	No. caught	Per cent dead after 24 hr.	No. caught	Per cent dead after 24 hr.	
Anopheles umbrosus	34	16	107	86	84
Mansonia spp.*	288	17	233	75	70
Anopheles barbirostris†	86	23	107	70	61
Anopheles sundaicus	107	14	62	66	60
Anopheles letifer	69	19	68	44	31
Culex vishnui	149	16	175	26	12
Culex fatigans	188	11	1,532	12	1

* About 80 per cent were *M. longipalpis*, the remainder mostly *M. uniformis* and *annulatus*.

† The 'dark-winged' form which is a vector of malaria.

some aspect of behaviour which prevents, or allows only a very brief, contact with the treated surfaces, rather than to innate resistance. *Anopheles gambiae* is killed by five seconds contact with DDT in the laboratory[3], but may escape unharmed from a treated hut[4].

The results with *Anopheles umbrosus* and the vectors of filariasis in Malaya (*Mansonia* spp.) are encouraging, but we need to know how long this dose of DDT remains effective against them. Any period less than three months would probably be uneconomic. The results against *A. barbirostris* and *A. sundaicus* are not very good, and against *letifer* they are disappointing. During the first three weeks after treatment 80–100 per cent of *barbirostris* and *sundaicus* were killed, but from the fourth week onwards the mortality dropped rapidly to 50 per cent or less. With *A. letifer*, even when the DDT was fresh, the kill scarcely exceeded 50 per cent. The mortality of *A. maculatus* during 6–9 weeks after treatment has been similar to that of *umbrosus*, somewhat more than 80 per cent.

Despite this insusceptibility of some species, one might suppose that so long as DDT prevents many mosquitoes from biting it will not matter if the majority are not killed; the insecticide ought still to be effective in controlling disease transmitted by such mosquitoes. Unfortunately, except with species of *Culex*, the biting-rate is only slightly reduced. Among the anophelines (including *maculatus*) and *Mansonia* captured in the window-trap huts, the biting rate is only lowered by about 10–20 per cent after treatment with DDT. *Culex* reacts very differently, DDT reducing the biting-rate by about 70 per cent. The contrast is so marked that it probably reflects an important difference in behaviour. It seems likely that *Culex* rests on the walls before biting, and that the anophelines and *Mansonia* do not. This would agree with one's personal experience of the biting behaviour of these mosquitoes, anophelines and *Mansonia* usually attacking in a manner that is rapid and direct compared to the cautious approach of *Culex*. Wallace has shown by direct observation that *A. maculatus* entering a trap hut mostly attack immediately without first resting on the walls[5]. There is some evidence that DDT spraying directed against *Culex fatigans* can reduce the transmission of bancroftian filariasis[6], and presumably this is due to DDT preventing the mosquitoes from biting rather than killing them. But if species which are vectors of disease are not prevented from biting by DDT, the insecticide is unlikely to reduce disease transmission unless it actually kills the mosquitoes, especially if, like anophelines in Malaya, they normally leave houses to rest out of doors by day. Even with a species such as *Anopheles gambiae* that commonly rests indoors, and is driven out of houses by DDT spraying, it appears that DDT may be ineffective unless it actually kills the mosquito. Experiments with trap huts have shown that under certain conditions DDT does not kill *A. gambiae* nor prevent it from biting[4], and in parts of East Africa four years of DDT spraying of houses has had very little effect on malaria transmitted by *A. gambiae*[7]. BHC, however, killed *A. gambiae* in trap huts and has reduced malaria in the house-spraying experiments. BHC also kills all Malayan species of mosquitoes that have been tested, including those mentioned in the table. But, except for *A. maculatus* and *C. fatigans*, we do not yet know how long the BHC continues to kill. A dose of 40 mgm. per sq. ft. of gamma BHC lasts as long against *A. maculatus* as the 200 mgm. dose of DDT, that is, about six months; but after five to seven weeks it kills fewer than 50 per cent of *C. fatigans*, and has lost all effect against this species after about nine weeks[1].

Nair[8], working in Malaya under the rather difficult conditions that existed in 1945–46, made a three months trial of house-spraying with DDT in kerosene in an area where *A. letifer* was presumed to be the vector. He considers that DDT can control malaria transmission by *A. letifer*, but in view of the results presented here a further trial appears necessary.

A recent report by Hadaway and Barlow[9] suggests that failure of DDT against *A. gambiae* may be due, at least in part, to its adsorption into the mud walls of the sprayed houses and experimental huts. BHC is also adsorbed in this way, so that no crystals remain on the surface; but it continues to kill by virtue of its fumigant action. This interesting discovery may possibly help to explain some of the contradictory reports about DDT and *A. gambiae*; for although Muirhead Thomson's experiments with trap huts showed DDT to be ineffective[4], other workers have obtained rather different results. Differences in the DDT formulations used, as well as in the construction of the trap huts, may also have been important. No such explanation is possible for the Malayan figures presented here, for the various species were exposed to uniform conditions, and often were caught in the same hut at the same time; for example, *A. umbrosus*, *letifer* and *Mansonia*, or *A. barbirostris*, *Mansonia* and *Culex*. The huts were of almost uniform design and all were lined throughout with a brown packing-paper called 'Sisalkraft'. We must believe, then, that there are real differences among species of *Anopheles* in susceptibility to DDT when applied as a residual spray in houses, though whether due to differences of behaviour or physiology we do not yet know.

It seems most desirable that tests with window-trap huts should form part of any scheme for malaria control by house spraying with residual insecticides. Admittedly the technique is not simple; the huts can be troublesome to operate and lengthy tests are necessary, but such huts appear to be the best method of finding out what we want to know, namely, the reactions of wild mosquitoes to the insecticides when applied in habitations, and the effective duration of the doses used. It is scarcely too much to say that something of the kind is indispensable for the rational planning of spraying programmes. In view of the many factors which, it now appears, can affect the mortality-rate of the mosquitoes, for example, the insecticide, its formulation and particle size, the nature of the treated surface, the species of mosquito and its behaviour, it will be important in future to keep conditions as uniform as possible throughout an investigation and to describe these conditions fully when reporting results. It would be interesting if tests could be made in trap huts with those vectors against which DDT house-spraying has already proved effective by reducing malaria, such as *Anopheles darlingi*, *albimanus* '*maculipennis*', *culicifacies* and others. Trap huts can also yield most important information on the behaviour and blood preferences of mosquitoes. The pattern of hut and method of operation used in Malaya have been described by Wharton[10]. [June 7.

EVALUATION OF CHEMOTHERAPEUTIC REMEDIES

THE Biological Methods Group of the Society of Public Analysts and Other Analytical Chemists held a symposium on the "Evaluation of Chemotherapeutic Substances" during October 26–27 under the chairmanship of Dr. G. M. Findlay. The chairman, in opening the discussion, emphasized the need for rapid and accurate methods of estimating the chemotherapeutic activities of the many hundreds of compounds which are now being prepared for the specific treatment of the parasitic infections of man and his domestic animals. The final and crucial tests can obviously be carried out only in man and his domestic animals; but preliminary laboratory tests are essential both for determining relative efficiency and for the accurate assay of substances already found to be effective. Improved methods are required for evaluating anthelminthics, fungicides, and compounds active against viruses.

The general problems involved in planning large-scale collaborative antibiotic assays to ensure adequate international standardization were dealt with by Dr. W. L. M. Perry. The relationship between technique and results, the 'over-accurate' assay, the homogeneity of estimates and the validity of the combination of results were discussed. At present, few laboratories use exactly the same technique for antibiotic assays. Dr. J. Ungar described the various types of *in vitro* and *in vivo* tests which must be carried out before a compound can be used in man. Acute systemic and local toxicities, as well as chronic toxicities, must be ascertained in several species of laboratory animals. The absorption and distribution in the tissues, normal and inflamed, and the mode of excretion are points of importance, as are the likelihood of sensitization and the interaction with other drugs. These remarks were illustrated by reference to 'estopen', a penicillin ester which is concentrated in the inflamed lung. Dr. J. Humphrey pointed out that, apart from good experimental design, the most important aim in assay methods involving diffusion of antibiotics into seeded agar plates is to obtain a sharp edge to the inhibition zones and a good slope. Penicillin and streptomycin give sharp edges with suitable organisms, due probably to the uptake or destruction of these antibiotics near the zone edge giving a steep concentration gradient. With the newer antibiotics the zones are less sharp. The factors determining slope are largely physical. Prof. J. M. Robson described the use of the rabbit's and mouse's eye for determining anti-tuberculous action: one great advantage is the safety of the method for all those performing the experiments. Dr. A. R. Martin discussed very fully the methods used in employing mice for screening anti-tuberculous compounds. The relation of the chick embryo test to the mouse test was described. Miss L. Dickinson gave details of anti-viral tests carried out in the developing chick embryo and in mice. Comparable results have been obtained in mice and chick embryos with the Nigg pneumonitis virus.

Dr. L. G. Goodwin described the use of weanling rats for the evaluation of amœbicidal drugs. His remarks were illustrated by a coloured film. The use of the infected rat provides a method which fulfils the essentials for a satisfactory amœbicidal test, for the infection is reproducible without fail, and untreated controls show a constant lesion; known remedies for the disease in man show a recognizable effect; the test takes only a short time and the infecting agent is derived from man and produces the same type of lesion in the rat. The only difficulty in the use of the rat is the presence of an amœba, *Entamœba muris*, which is not affected by amœbicidal drugs. Special precautions must be taken to prevent infection of the rat colony with *E. muris*.

Dr. J. D. Fulton reported on the various media used for the growth of pathogenic amœbæ *in vitro* and their possibilities for providing methods for testing amœbicidal drugs. The question was discussed whether these amœbicidal drugs act directly on the amœbæ or indirectly on the bacterial flora which provides the pabulum for the amœbæ. The possibility of using *Trypanosoma cruzi* in place of bacteria for the nutrition of the amœbæ was described. Dr. E. M. Lourie pointed out that refined statistical methods are invaluable for biological standardization, but in the search for new compounds of value clinically they are useless if inappropriate experimental procedures are used. In Africa, in the control of trypanosomiasis, mass treatment is giving way to mass chemoprophylaxis, and new compounds are being devised for this purpose. There is therefore urgent need for a simple and rapid method for screening compounds in regard to their prophylactic activity. There is difficulty in standardizing trypanocides of the melaminyl series by chemical or physical means. Standard preparations of these substances are required, and batches intended for use in man should be biologically tested in relation to these standards.

The various laboratory tests, with monkeys, birds and mice, employed for the evaluation of anti-malarial compounds, were described by Dr. D. G. Davey. Regard must be had for the fact that, except possibly in the case of *Plasmodium malariæ*, none of the malarial parasites in man has been established in laboratory animals. The tests used, nevertheless, are unlikely to pass over any compound of potential value in man. Dr. Ann Bishop pointed out that quinine gives rise to little or no drug resistance, and with pamaquin only a very slight increase can be induced. Proguanil, however, readily induces resistance in *Plasmodium gallinaceum*; strains treated with sulphadiazine or sulphanilamide become resistant to themselves and to proguanil. Metachloridine also induces a high degree of drug resistance in malarial parasites. In testing for ability to produce drug resistance, experimental strains of the parasite must be maintained in a state of acute infection. Results from tests upon latent infections are not comparable and are difficult to evaluate.

Dr. F. Hawking urged that when a compound has once been shown to be effective in the laboratory, it should be tested as soon as possible in man in order to bring to light toxic reactions which cannot be elicited in laboratory animals.

IMPORTANCE OF SCIENCE IN AMERICAN EDUCATION

IN a paper contributed to *Science* (113, 2945; June 8, 1951) Ernst A. Hauser, of the Massachusetts Institute of Technology and the Worcester Polytechnic Institute, suggests that most of the advances in science in pure or fundamental research have been made by citizens of countries other than the United States or by American citizens who have received their education in Europe or by Europeans who have emigrated to the United States. In a supporting statement, Hauser quotes the president of the American Society of Mechanical Engineers, who recently declared that the American failure to recognize and respond to their particular responsibilities as citizens and human beings and their failure to understand that technical progress is not enough is the key to many of the greatest difficulties in America to-day. Recently, the United States Commissioner of Education has also directed attention to the fact that a great number of educational institutions still organize their curricula in water-tight compartments, and that all efforts to penetrate the barriers between departments are jealously resisted.

In an attempt to discover the weaknesses in the science side of American education, Hauser compares a German and an American university. In the latter the student is permitted to devote himself to a specialized branch of science or technology far too early, so that the last college years are used as preparation for an advanced specialized education, thereby cutting down the time that should be devoted to general education. Another essential difference between American training technique and that used in Europe is that Americans use systematic drilling as a method of instruction; this can provide sound knowledge, but is scarcely likely to promote self-reliant thinking and the spirit of research. The excessive use of the text-book may also be criticized because it works in the same direction. Throughout most of Europe only those who have graduated from the *Gymnasium* or *Realschule* may enrol in a university or comparable technological institute. When graduating from one of these schools, which they have had to attend for eight years (having left the grammar school at about ten or eleven), students have acquired a background of general education at least comparable to that of American students starting the junior year in college.

Hauser suggests that what is needed in American education is to offer all students a more general appreciation of what science actually stands for. With J. B. Conant he agrees that the objective should be to give a greater degree of understanding of science by the close study of a relatively few historical examples of the development of science. Case-histories, he suggests, would almost all be chosen from the early days in the evolution of the modern discipline, as, for example, certain aspects of chemistry in the eighteenth and nineteenth centuries. The advantages of this method of approach are two-fold: first, relatively little factual knowledge is required either of the science in question or other sciences, and relatively little mathematics; second, in the early days one sees in clearest light the necessary fumblings of even intellectual giants when they were also pioneers; one comes to understand what science is by seeing how difficult it is in fact to carry out pretentious scientific precepts.

Hauser also concurs with I. B. Cohen, of Harvard, who quite recently said that students could be given a general appreciation of what science stands for by making them more familiar with the human side of those to whom we owe the greatest discoveries in science, and with the circumstances that led to the accomplishments for which they are now famous.

CURRENT TRENDS IN GENERAL PSYCHOLOGY

THE programme for the morning session on August 9 of Section J (Psychology) of the British Association consisted of three papers discussing tendencies in general psychology. The discussion presents certain difficulties to anyone attempting to summarize it, in that the three papers were diverse in content. Prof. R. C. Oldfield was concerned with experiment in psychology; Prof. A. Rex Knight and Mr. A. J. Laird with motivation; while the present writer dealt with the teaching of psychology. Instead of a summary, therefore, an attempt will be made to discuss rather generally certain tendencies in present-day psychology which the papers seemed to reveal.

It is clear that, by the middle of the present century, psychology has outgrown certain early phases. These phases were first of all the period of the 'schools', when psychologists carried on the disputative traditions of their philosophical predecessors. There followed a phase of rather indiscriminate experimentation which was corrected after a time by a preoccupation with problems of method. More recently there has been a tendency for those interested in theory and experiment to dissociate themselves from the testers and statisticians, on one hand, and the clinicians, on the other. To-day, however, there is a considerable measure of unity, and experimental techniques are being used which are varied and flexible enough to cope with a wide range of problems.

Prof. Oldfield mentioned two investigations which show the present-day trend. In the first, attempts are being made to use rather complicated mathematical tools in describing the behaviour of a maze-running animal at a point of choice; and in the second, an analysis is being made, again using quite advanced mathematics, of certain visual illusions first investigated by Ames in the United States. Both these investigations are of great theoretical interest in themselves. But in addition, as Prof. Oldfield pointed out, they throw light on human behaviour in its everyday setting or in the clinic.

Prof. Knight and Mr. Laird were concerned to show that some rather naïve methodological assumptions about human motivation have led to logical difficulties. They suggested other interpretative schemes free from these difficulties. Again, it was emphasized that theoretical considerations of this kind are directly related to practical and clinical problems.

Finally, the present writer pointed out the increasing demand for professional psychologists and the inadequacy of present training methods in Great Britain to meet that demand. He suggested that the most useful development would consist in the expansion of training at the graduate level. It was agreed, however, that professional training should not be allowed to develop at the expense of fundamental research, nor should it be dissociated from the consideration of theoretical problems. Recent developments suggest that a good deal of research which has itself no directly practical aim will be of relevance in the practical field.

So far as any trend in general psychology was revealed by the three papers, it was this: that the different schools and aims and methodologies of psychology are disappearing, and the field is becoming much more unitary than was the case during the first part of the present century. J. Drever

BRITISH MEDICINE AND THE CONTINENT, 1600–1850

A NEW exhibition at the Wellcome Historical Medical Museum—"British Medicine and the Continent, 1600–1850"—presents some interesting contrasts with the "Medicine in 1850" exhibition which it has replaced. The latter exhibition dealt with the medicine of Europe during a limited period, and was, in effect, a cross-section of medical thought. The new exhibition is designed to illustrate not so much the state of medicine at various times in different countries, as the fluctuating influence which the medical and scientific thought of the European Continent exercised on British medicine at different times, and *vice versa*.

A limited aspect of this approach was well brought out by Prof. Edvard Gotfredsen, professor of the history of medicine in the University of Copenhagen, in his address at the official opening of the exhibition, which took place before a distinguished company on October 19. Prof. Gotfredsen chose to deal with the relations between British and Danish medicine in the seventeenth and eighteenth centuries. He pointed out that in the seventeenth century medicine was very international, and that, as Latin was the international language of learning, medical students were enabled to travel all over Europe to hear famous teachers. Danish students of medicine of that time were forced to go abroad for much of their education, since a full medical education could not then be obtained at the University of Copenhagen. Of the Danish medical students who later became famous, those who visited Great Britain included Caspar Bartholin the elder, who wrote an important work on medical education and recommended foreign travel. Caspar's son Erasmus visited London and Oxford in 1647, and his brother-in-law, Olaff Worm, stayed for a year and a half in England.

The impact of Harvey's doctrine of the circulation was important in Denmark, since the new theory was introduced into that country by Thomas Bartholin, who also had considerable influence in spreading it on the Continent. The Dane, Holger Jacobæus, who later became professor of anatomy at Copenhagen, left some interesting descriptions of his life in London and Oxford. Prof. Gotfredsen also described in some detail the difficulties which arose in the Royal Society in attempts to confirm Stensen's work on the effects of ligating the descending aorta. In the first half of the eighteenth century the travels of Danish students had become less extensive, and in the second half they practically ceased. This fact was due to the improvement of facilities for clinical instruction in Copenhagen.

Prof. Gotfredsen was introduced by Dr. E. Ashworth Underwood, director of the Wellcome Historical Medical Museum, and a vote of thanks to him for his address was proposed by Sir Wilson Jameson.

The exhibition commences with the British and Continental background at the end of the sixteenth century. This extremely interesting period, which was the prologue to all that followed in the seventeenth century, was marked by the overwhelming importance of Paris, Montpellier and Padua. Of the English works of this period, mention should be made of the superb copy of the 1545 edition of the "Anatomy" of Geminus. Another rare work which is shown, and which itself had considerable influence on the Continent, was Mouffett's "Theatre of Insects", 1634. One of the rarest books shown in this exhibition is the first edition of "The byrth of mankynde"; this is the translation of the well-known book by Eucharius Roesslin. This first edition was published in 1540 and the copy shown is one of the very few perfect copies in existence.

It need scarcely be said that the section of the exhibition on Harvey contains fine first editions of his works. Harvey's influence on the medicine of the Continent is brought out by the published works of his supporters and of his opponents.

The rise of the Royal Society is shown in an interesting manner, as also are its connexions with the scientific men of the Continent. In the later sections Boerhaave and Haller are well represented by fine copies of their works and a number of relics. The influence of the Hunters dominates the second part of the period dealt with, and in this connexion many will be interested in the extra-illustrated edition of Jesse Foot's "Life of Hunter". This contains many original wash drawings which illustrate events in the life of John Hunter.

The later sections of the exhibition contain books and exhibits which are now classics of the late eighteenth and early nineteenth century developments of the sciences which form the fundamental basis of modern medicine.

The Term 'Regular Solution'

In 1920[1] I directed attention to the fact that the solubility of solids, plotted as a logarithm of mole fraction against reciprocal temperature, gives a family of curves in the case of solutions "where no molecular changes are involved". In 1927[2] I designated such solutions as 'regular' and in 1929[3] I discussed the thermodynamic significance of this regularity, stating, in part: "From our picture of a regular solution as one in which orienting and chemical effects are absent, and in which the distribution and orientations are random, just as in an ideal solution, we may conclude that the probability of X_2 [species 2] is the same in the two solutions [ideal and actual] and, therefore, that the difference in entropy is zero. We cannot expect this conclusion to hold unless the random distribution of molecules persists. We may expect further that a small correction should be applied to take care of the change in entropy accompanying changes in volume, given by $(\partial S/\partial V)_T = (\partial P/\partial T)_V$; or we may state our principle in the following form. A regular solution is one involving no entropy change when a small amount of one of its components is transferred to it from an ideal solution of the same composition, the total volume remaining unchanged."

I referred to the possibility of expressing the partial molal enthalpy (of component 2) by the Margules series, $bx_1^2 + cx_1^3 \ldots$, but showed that the behaviour of many solutions can be adequately expressed by the first term alone. It became evident, soon after[4], that the mole fraction should be replaced by the volume fraction, and the coefficient b was evaluated in terms of the pure components.

The term 'regular solution' has now come into general use, but not always in conformity with the above definition. For example, Guggenheim[5] uses it as follows: "We now turn to a class of mixtures called *regular mixtures* or *regular solutions* defined by the properties $\log f_1 = wx^2/RT$—wherein w is not merely independent of the composition but independent of the temperature.—The name *regular solution* was first used by Hildebrand." Rushbrooke[6] writes a certain partition function and says, "A solution for which the partition function is given by equation (8) is known as a *regular solution*". Longuet-Higgins[7] states, "This theory [of regular solutions] assumes that in a liquid mixture (*a*) the molecules are arranged in a regular lattice, (*b*) that the separate liquid components have ordered structures of the same type and (*c*) that the intermolecular potential energy is the sum of contributions from nearest neighbours in the lattice, the contribution of two neighbouring molecules depending only on their chemical nature".

I cite these differences not for the purpose of asserting my rights as the inventor of the term but to urge that so useful a concept, to which a simple definite meaning was originally attached, should not be robbed of its significance by different writers re-defining it each in his own way. I have no objection to a re-definition that may appear desirable in the light of present knowledge; but it should be made by general consent.

One question does arise in connexion with the original definition, wherein ideal entropy and random distribution of molecules were regarded as equivalent. We have since learned from a succession of investigators, culminating with Flory and Huggins[8], that the entropy of mixing molecular species of significantly different size, even though randomly mixed, is not the ideal entropy; therefore, we should decide whether to attach the term 'regular solution' to one or the other of these concepts. Prof. Scott and I, in our "Solubility of Nonelectrolytes" (third edition), have used it to mean ideal entropy, for example, the partial molal entropy of transfer $\bar{S}_1 - S_1^0$ from pure liquid to solution of mole fraction x_1 is $\bar{S}_1 - S_1^0 = -R\ln x_1$. This is more restricted than the other definition, but except for solutions of high polymers, it holds well enough for many purposes and permits expressing the activity coefficient in terms of the enthalpy. The Flory–Huggins equation involves certain assumptions that prevent it from being regarded as an accurate expression of the concept of complete randomness. To define the regular solution in terms of ideal entropy better fulfils the function of a useful reference state, well explained by Scatchard[9]: ". . . The student should be taught that thermodynamics deals with differences, that the number of differences to be considered can be reduced greatly by the use of reference states, that the magnitude of the differences can be reduced by the use of deviation functions, and that the choice of reference states and of deviation functions is entirely a matter of convenience, which should not be allowed to reduce the accuracy of any calculation . . .".

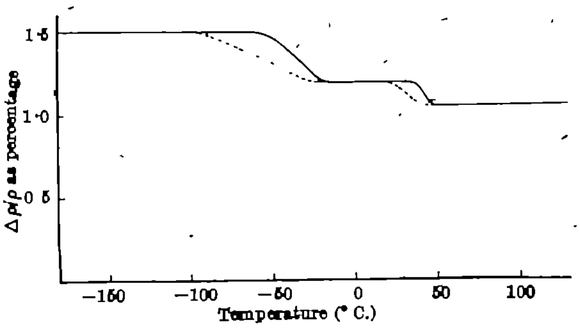
Change of Resistivity of Gold by Cold-working at Liquid-Air Temperature and its Recovery by Temporary Heating

Some time ago Molenaar and Aarts[1] observed that the increase of the resistivity of copper, silver and aluminium wires, caused by a plastic deformation at liquid-air temperature, decreased on keeping the wires at room temperature. The recovery of the resistivity was not accompanied by a recovery of the mechanical properties. The stress–strain curve at liquid-air temperature was not changed by this temporary heating.

We have now measured the recovery of the resistivity of gold wires. A gold wire, which had been soft-annealed, was stretched approximately 7 per cent at liquid-air temperature and its resistance measured. This elongation caused a relative increase of the resistivity of about 1·5 per cent. The wire was then warmed up to different temperatures, at



which it was kept for some time. After this treatment the resistance of the specimen was measured again at liquid-air temperature.

The accompanying graph shows the recovery of the resistivity as a function of the 'heating temperature'. The curve drawn is for a heating time of 2 min., while the dotted line gives the results for a heating time of 5 min. (The curves are quantitatively rather rough, as the time necessary for bringing the wire to the 'heating temperature' cannot be neglected.)

It is evident that two processes occur. At about − 50° C., the extra resistivity starts to decrease from 1·5 to about 1·2 per cent, and at about + 35° C. from 1·2 to about 1·05 per cent, when the heating time is 2 min. For a heating time of 5 min., both recovery steps start at lower temperatures.

The stress–strain curve is not changed by this heating.

As a possible explanation of these results, we suggest, following an idea of F. Seitz[2], that the extra resistivity which disappears at about + 35° C. (20° C.) is due to vacant lattice sites, while that which disappears at about − 50° C. (− 100° C.) is due to conglomerates of two or more vacant places. These vacant sites are formed during the cold-working. The absence of any change in the mechanical properties suggests that the dislocations, which are responsible for the strain-hardening, do not change at these temperatures.

We wish to thank the Delftsch Hoogeschool Fonds for its financial support.

Elastic Constants of Alkali Halide Crystals

ADOPTING the simple Born model for an alkali halide crystal, in which the ions are regarded as held in their respective positions by the electrostatic and the repulsion interactions between the ions, one may readily calculate the velocities of propagation v of long acoustic waves of wave-length λ along the principal directions [100], [110] and [111], and hence along any direction, in the crystal:

$$v^2 = \sum_n (A_{1n}\Delta^2_{1n})/(m_1 + m_2), \qquad (1)$$

where m_1 and m_2 are the masses of the two ions, $2\pi\Delta_{1n}/\lambda$ denotes the difference in phase of the acoustic wave at any two ions 1 and n, and $\sum\limits_n$ denotes summation over all the ions, except 1, in the crystal. (If D is the distance up to which the electrostatic interactions remain significant, λ is regarded as sufficiently large in comparison with D that $\cos(2\pi D/\lambda)$ can be put equal to $1 - \frac{1}{2}(2\pi D/\lambda)^2$.)

$$A_{1n} = (\psi'/R_{1n}^0)(1 - Q^2) + \psi'' Q^2, \qquad (2)$$

where $\psi(R_{1n})$ is the interaction energy between the two ions 1 and n, separated by a distance R_{1n}, and ψ' and ψ'' are its differential coefficients with respect to R_{1n} at its equilibrium value R_{1n}^0. Q is the cosine of the angle between R_{1n}^0 and the direction of displacement of the ions under the acoustic wave. Since the values of v^2 for different directions of propagation and corresponding directions of displacement are also known in terms of the elastic constants c_{11}, c_{12} and c_{44}, we obtain, by comparing them with the values obtained from (1), expressions for the elastic constants in terms of the interactions between the ions. We shall denote by ε_{11}, ε_{12}, ε_{44} the contributions to c_{11}, c_{12}, c_{44} respectively from the electrostatic interactions, which are of long range, and by ρ_{11}, ρ_{12}, ρ_{44} the contributions from repulsion interactions, which are assumed to fall exponentially with the increase in the distance of separation of the interacting ions. In view of the short range of these repulsion interactions, we regard them as confined to the immediate neighbours only.

Let us first consider a crystal of the sodium chloride type, and take the co-ordinate axes along the cubic axes of the crystal, and the origin at the equilibrium position of ion 1. It is found that the ε's and the ρ's can be expressed in terms of the following two series, in which ξ, η, ζ are integers, which, multiplied by d, the sodium–chlorine distance, define the co-ordinates of all the lattice points:

$$\Sigma(-1)^{\xi_n+\eta_n+\zeta_n}/(\xi_n^2 + \eta_n^2 + \zeta_n^2)^{1/2} = -\alpha, \text{ say}, \qquad (3)$$

which can be recognized as the Madelung series, and

$$\Sigma(-1)^{\xi_n+\eta_n+\zeta_n}(\xi_n^4 + \eta_n^4 + \zeta_n^4)/(\xi_n^2 + \eta_n^2 + \zeta_n^2)^{5/2} = -\chi, \text{ say}, \qquad (4)$$

which also is a known series[1]. It is further known that $\alpha = 1{\cdot}748$ and $\chi = 3{\cdot}139$. The values of the elastic constants thus calculated, which refer to very low temperatures, are given in the following table in terms of $e^2/(12d^4)$, in which e is the electronic charge. δ in the table is a number such that d/δ gives the distance over which the repulsion interaction drops to $1/e$ of its value ($\delta = 9$ in the case of sodium chloride).

	11	12	44
ε	$2\alpha - 6\chi$	$-5\alpha + 3\chi$	$-\alpha + 3\chi$
ρ	$2\alpha\delta$	2α	-2α
c	$2\alpha(\delta + 1) - 6\chi$	$-3\alpha + 3\chi$	$-3\alpha + 3\chi$

Since the interaction forces have been assumed to be central, c_{12} naturally comes out equal to c_{44}, though ε_{12} and ρ_{12} are not separately equal to ε_{44} and ρ_{44} respectively. The final values for the c's are the same as those obtained by Kellermann[2] and also agree with the experimental values. Our values of ε_{12}, ε_{44} and of ρ_{12}, ρ_{44}, however, differ from his.

Similar expressions are obtained from the cesium chloride type of crystals, in terms of two series α' and χ' that are similar to (3) and (4).

It is remarkable that for the sodium chloride type, c_{11} and c_{44}, as also the corresponding ε's and ρ's, depend on the lattice constant alone. This result, however, does not hold for the cæsium chloride type.

Calibration of Geiger-Müller Liquid Counters by the Radioactivity of Potassium-40

IN recent clinical radioactive tracer studies using sodium-24, phosphorus-32 and iodine-131, it was found desirable to have a reliable and convenient radioactive standard, of similar beta- and gamma-ray energy, easily reproducible, of negligible radioactive decay and with adequate carrier protection against exchange reactions upon the glass walls of Geiger–Müller liquid counters[1]. The radioactive isotope, potassium-40 of normally occurring potassium, is present to one part in 9,000 and has a half-life of $12 \cdot 7 \pm 0 \cdot 5 \times 10^8$ years[2] with a beta-ray spectrum of maximum energy 1·33 MeV. and a gamma-ray of energy 1·5 MeV.

Some time ago, Barnes and Salley described[3] a method for the analysis of potassium by its natural radioactivity, using a Geiger–Müller liquid counter calibrated with standard potassium solutions. The time required, from statistical theory, for a measurement with probable error of ± 1 per cent for a 4 *N* potassium chloride solution in a 20-ml. counter was about 70–80 min. In my early experiments, concentrated solutions of potassium chloride were used for calibrating counters. Later it was found that concentrated solutions of potassium carbonate gave nearly three times the counting-rate of concentrated potassium chloride. The most convenient compound from the point of view of solubility and potassium concentration was found to be potassium carbonate, which at 20° C. has a solubility of 112 gm. per 100 ml. water.

A type *M6* 10-ml. Geiger–Muller liquid counter filled with standard potassium carbonate solution gives 550 counts/min. with the counter enclosed in a protective lead screen. The background count is by comparison 15 counts/min. Other solutions, of potassium bromide and iodide, have also been tried, but, owing to the lower solubility and small concentration of potassium, give lower counting-rates. Solutions of potassium hydroxide may be used to give a 20 per cent greater counting-rate than potassium carbonate, but are much less convenient in manipulation.

It is therefore suggested as a basis of international standardization of Geiger–Müller liquid counters that they may be calibrated with standard potassium carbonate solutions with an accuracy of ± 1 per cent in 8 min. counting time.

A standard solution can be made up from 100 gm. analytical reagent potassium carbonate anhydrous (after heating to 200–300° C.) dissolved in 100 ml. distilled water. The advantage over standard solutions of cobalt-60 hitherto used[4] for counter standardization is that there is low cost, and the carbonate is universally available, has negligible radioactive decay and gives no residual activity in the counter due to adequate carrier protection.

Propagation of Very-High-Frequency Radio Waves

DURING the period autumn 1949 – spring 1950, a series of measurements of field-strength from a very-high-frequency airborne transmitter was made at the Royal Aircraft Establishment. The main purpose of the investigations was to examine the field-strengths obtained in varying weather conditions with one end of the propagation path at a height of 40,000 ft. above the earth (the other end being at a height of 90 ft.) and to compare them with the field-strengths calculated from conventional ray-theory for a smooth spherical earth for both ordinary and four-thirds earth radius. For this purpose the two frequencies 280·2 and 386·6 Mc./s. were chosen.

In the curves of field-strength, plotted against distance between transmitter and receiver for those cases where the indirect ray was reflected from land, the observed minima were in some cases shallower than the calculated values, as could be expected for reflexion from a rough surface, but in no case were they deeper. Fig. 1 is a typical curve for land reflexion. In all instances, however, where the indirect ray was reflected from the sea, as in Fig. 2, the observed minima were considerably deeper than the calculated values, and this feature was also present

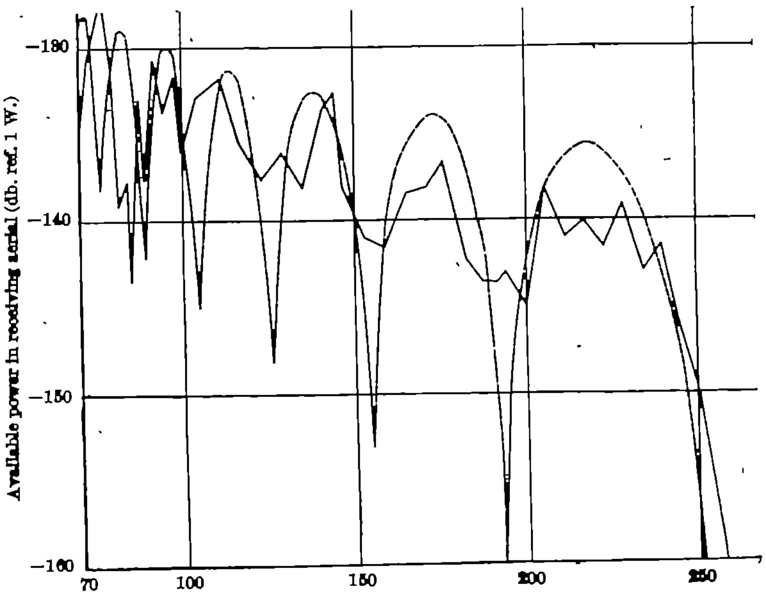

Fig. 1. 386·6 Mc./s., over land: ----, calculated; ——— measured

in two observations made with the transmitter at a height of 10,000 ft.

It was also noted that in about 90 per cent of the observations there was closer agreement between curves of observed and calculated field-strengths for both land and sea reflexion of the indirect ray, when the earth's radius was taken at its ordinary value rather than the conventional four-thirds value to allow for 'normal' atmospheric refraction.

The permittivity and conductivity of earth were taken as 10 electrostatic units and 10^{-13} electromagnetic units respectively, and, for sea, as 81 e.s.u. and $4 \cdot 6 \times 10^{-11}$ e.m.u. respectively, in the calculation of reflexion coefficients. The abnormally deep minima in the case of sea reflexion are equivalent in some cases to an apparent increase in reflexion coefficient by a factor of 2·25, and the discrepancy between observed and calculated values decreases with decrease in the angle of incidence of the indirect ray on the sea; that is, it attains a maximum value with maximum distance between transmitter and receiver.

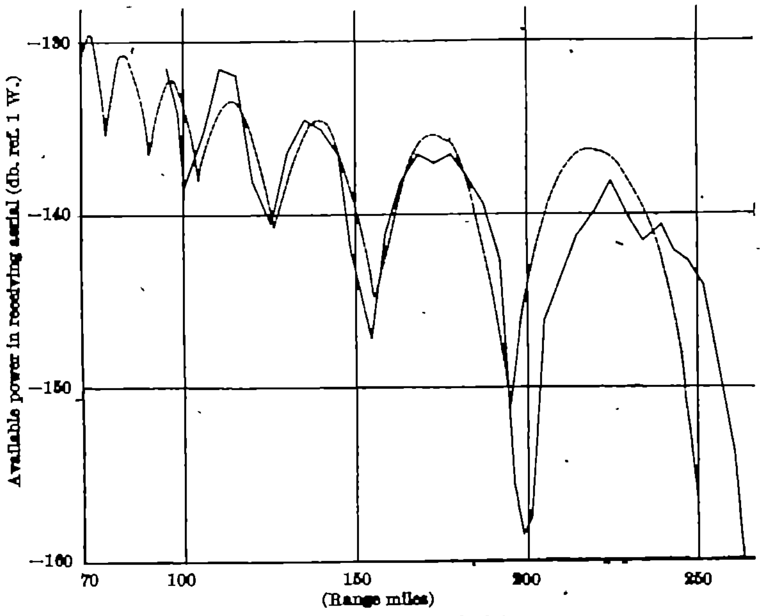

Fig. 2. 386·6 Mc./s., over sea: ----, calculated; ——, measured

The topography of the cliff site chosen for the investigations over sea was such that no reflected ray from local objects or land-masses could account for the additional energy necessary to produce the large apparent increase in reflexion coefficients; and any abnormal increase in atmospheric refraction would have tended to produce shallower minima, since angles of incidence at a given distance would have been reduced and thereby reduced the corresponding reflexion coefficients. Any inertia in the recording instruments employed would also have tended to make minima shallower.

The weather conditions during the investigations varied from settled, anticyclonic types to low-pressure, unsettled weather with considerable variation of temperature, humidity and wind.

Reduction of Static Electrification by means of Inhibiting Compounds

In connexion with the problem of static electrification in the processing of nylon fibre, we have undertaken a study of the factors involved in the reduction of static charges by means of 'antistatic agents'.

The work of Coehn[1] and Richards[2], coupled with that of Gill and Alfrey[3], indicates that such electrical charges are generated by the the transfer of electricity between two bodies of different dielectric constant, induced by a natural field which sets up a contact potential at the interface when the bodies are brought into contact. The transfer takes place in a direction such that the contact potential is neutralized, and the charges become evident only on subsequent separation of the two bodies. The high voltages encountered are due to the drop in capacity of the system on separation of the bodies according to the well-known law, the charge actually remaining the same as when they were in contact.

An apparatus was constructed which gave reasonably quantitative measurements of the electrostatic effect of rubbing nylon yarn against a metal surface. A 2-gm. hank of nylon was rubbed back and forth over three metallic rods by means of an eccentric revolving at 60 r.p.m. The outer rods were of steel and connected to earth. The central rod was of brass and connected to one terminal of a voltage-measuring device, the other terminal of which was earthed. The relative humidity of the surrounding atmosphere was controlled to 29 ± 1 per cent. In operation the voltage was read after 60 strokes of the hank. Under controlled conditions, voltage measurements were consistent within 2 per cent. The earthed steel rods contributed considerably to the reproducibility of the results. They appeared to restore the nylon to a standard electrical state after each passage over the brass rod.

Figs. 1 and 2 show the results obtained for five liquids when applied to nylon in increasing amounts. When a new liquid was to be tested the rods were cleaned with acetone. Two types of curve will be noted. The smooth curves in Fig. 1 show a variation with the dielectric constant (*D*). The liquid having the higher constant seems to be the more effective at small amounts on the yarn in reducing the genera-

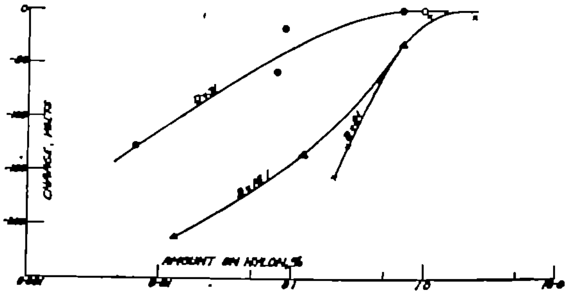

Fig. 1. Effect of dielectric constant *D* on charge

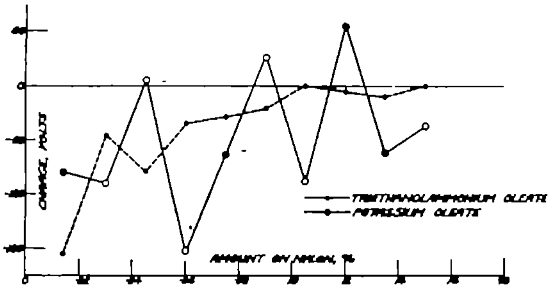

Fig. 2. Effect of surface activity on charge

tion of electrical charges. It may be that water owes its effectiveness for this purpose to the comparatively high dielectric constant ($D = 81 \cdot 5$). Liquids of the surface-active type appear to give a second class of curve. Two examples, chosen from a large number, are illustrated in Fig. 2. These curves follow the general trend of those of the first class, but show a peculiar periodicity, often with a reversal of sign of the electrical charge. This would seem to be an expression of the existence of molecular layers, since the change in amount of liquid between the peaks and valleys on the curve approximates to that required to deposit a monomolecular layer on the nylon. From the reversals in sign it would seem that the dipoles are oriented alternately in direction. Electrical charge is finally eliminated when the layer of antistatic agent is sufficiently thick to allow the outer surface to behave as an isotropic liquid. This effect is illustrated by triethanolammonium oleate. Potassium oleate, on the other hand, appears to be laid down in much more rigid layers and, in the example given, is not present in sufficient quantity to behave as an isotropic liquid. The most effective of this class of antistatic agent seem to be those which combine (*a*) a dipole of such a strength as to limit the field due to the nylon within several layers of the surface, and (*b*) a degree of surface activity which allows random orientation at small amounts.

The experimental results allow us to speculate on the mechanism by which antistatic agents function. If a body, covered by a film of antistatic agent, meets a second body, a thin film of antistatic agent separates the two. The antistatic agent limits the fields of the bodies to a short distance within the film, so that interaction of the fields is impossible and no contact potential is created within the body of the film. If, on subsequent separation, the division takes place within this section of the film, then no significant static charge results since, in effect, like materials have been separated. The more effective the antistatic agent is in limiting the field the more effective it is in reducing static charges.

Examination of the curve for potassium oleate seems to give information on the mechanism of generation of static electricity as well as that concerning antistatic action. It will be noted that considerable voltages are indicated at points where the influence of the nylon must be comparatively small. These voltages seem to be due to dipoles fixed in position by orientation with the nylon acting as a support only. Therefore, one might conclude that one type of generation of static electricity, at least, is due to the action of dipoles in fixed orientation at or near the interface of bodies in contact.

The advice and criticism of Dr. J. H. Michell is gratefully acknowledged. We are indebted to Canadian Industries, Ltd., for permission to publish this communication. A detailed account of the work will be published elsewhere.

Temperature Dependency of Half Line-Width in Ferrite

An experimental investigation of half line-width in ferromagnetic resonance absorption at various temperatures has been carried out by Bloembergen[1], using some ferromagnetic metals. The results were compared with the theory by Van Vleck[2].

In order to clear up the real nature of half line-width in the ferromagnetic resonance experiment, it is desirable to investigate the temperature dependency of line shape in an insulator.

In the present work, half line-widths have been determined for some ferrites, $MgOFe_2O_3$, $CuOFe_2O_3$, $MnOFe_2O_3$ and $NiOFe_2O_3$, in a resonance experiment over a temperature-range of − 195° to the Curie point, using thin specimens in the form of disks, and a wave-length of 3·2 cm.

The results for these materials show almost the same tendency with varying temperature; the changes of line-width for $MgOFe_2O_3$ and $CuOFe_2O_3$ only are shown in the accompanying tables.

$MgOFe_2O_3$. Curie point, 432° C.

Temp. ° C.	−190	−130	−110	−82	−50	16	51	79	124	164	204	242	281	320	356	390	398
Line-width (Oe.)	840	680	640	588	502	435	388	338	316	270	240	200	160	157	116	98	97

$CuOFe_2O_3$. Curie point, 430° C.

Temp. ° C.	−176	−145	−122	−99	−87	−65	−50	−20	20	62	102	110	147	210	260	310	362	400	410
Line-width (Oe.)	800	700	609	550	520	482	465	420	350	315	258	265	240	200	190	170	137	122	122

Generally speaking, the half line-width decreases monotonously with increase of temperature; the line-width becomes narrower at temperatures near the Curie point; afterwards the resonance suddenly disappears above the Curie point. The results are quite contrary to the case of ferromagnetic metals.

Details of the apparatus and procedure will be published in *Sci. Rep. RITU*.

Hüttig's Adsorption Isotherm

Three years ago, Hüttig[1] derived a multilayer adsorption isotherm which in most cases agrees with experiment up to higher relative pressures $x = p/p_s$ (where p_s is vapour pressure of the liquid adsorbate) than the Brunauer–Emmett–Teller[2] isotherm. Hüttig's formula, however, is not in accord with the kinetic assumptions implied in the derivation and does not explain the entire failure of the theory at very high pressures (x greater than 0·8).

The kinetic assumption underlying Hüttig's theory is that *all* molecules of each layer may evaporate, whereas in the Brunauer–Emmett–Teller theory only uncovered molecules are allowed to do so. Hüttig's mechanism of desorption is rather unrealistic from the point of view of the multilayer model in which the adsorbed molecules are arranged in vertical chains. To permit a lateral evaporation of covered molecules, these vertical chains must be arranged rather loosely, and one can scarcely assume that such an arrangement would be in a stable equilibrium. Further, if a covered molecule evaporated from the lower part of a vertical chain, this chain would collapse or at least re-arrange itself, so that the net result would again be evaporation from the top of the chain.

This difficulty can be removed in the following way. We consider a surface on which adsorption occurs only at localized centres separated from each other by surface regions with negligible attractive power for the adsorbate. The distance between the centres should be at least one or two molecular diameters. Then the vertical chains of the multilayer model turn over into the surface, where they form essentially two-dimensional clusters around the localized centres. In this model the concept of several layers loses its meaning. We can distinguish only between the molecules adsorbed on the localized centres (first layer) and additional molecules (higher layers). We shall, however, retain Hüttig's formalism in which the different layers are distinguished. It appears that for this model Hüttig's mechanism of evaporation is quite satisfactory. A proof of this assumption can be derived, however, only from a rigorous statistical treatment of the model. The statistical equivalent to Hüttig's formalism will be investigated elsewhere.

Quite independent of the special condition of desorption, there is still another, much more general, argument for the proposed cluster model. It has been shown by Halsey[3] that two-dimensional condensation within the first layer occurs earlier than the formation of higher layers in all cases where the surface centres are close enough together to exclude the cluster model suggested here. Hence it appears that this latter model is the only one which fits the formalism of Brunauer–Emmett–Teller or Hüttig.

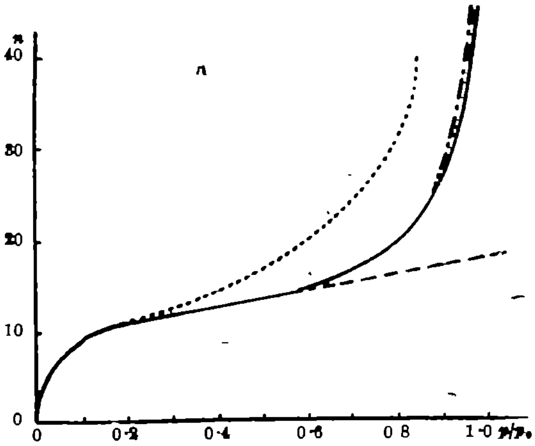
Concerning the failure of Hüttig's isotherm for very high pressures, we assume that this failure is the result of the simplification that the affinity constants K_1 and K (see equation 1) or, in other words, the conditions of evaporation, do not depend on the number of adsorbed molecules. This simplifying assumption can be modified in a semi-empirical way by the following considerations. The clusters, which are essentially two-dimensional at low pressures, will gradually overlap and grow vertically to the surface if the pressure is increased. The result will be that a certain fraction n' of the n adsorbed molecules will be entirely enveloped by other molecules, and hence unable to evaporate. If we put $n' = nx^s$, Hüttig's velocity of desorption $K_i''n$ is transformed to $K_i''n(1 - x^s)$ and the affinity constant $K_i = K_i'/K_i''$ is transformed to $K_i/(1 - x^s)$. Introducing this expression into Hüttig's formula (1) (where n_s is number of surface centres),

$$\theta = \frac{n}{n_s} = \frac{K_1 p}{1 + K_1 p}\,(1 + Kp)\,; \qquad (1)$$

and putting $K_1 p = Cx$ and $Kp = x$, we obtain:

$$\theta = \frac{Cx}{1 + Cx - x^s} \cdot \frac{1 + x - x^s}{1 - x^s}. \qquad (2)$$

Equation 2 is the formula for the cluster isotherm in the notation of the Brunauer–Emmett–Teller theory. It is a generalization of formulæ which are the limiting cases for $s = 1$ (Brunauer–Emmett–Teller) and $s = \infty$ (Hüttig). Since in Hüttig's theory the number of chains containing s adsorbed molecules is about $n_1 x^s$ (n_1 is number of molecules in the first layer), s can be interpreted as the average number of molecules necessary to envelop entirely a molecule of the first layer. Hence the reciprocal of s measures the tendency of the essentially two-dimensional clusters partly to grow vertically to the surface. $1/s$ is zero for Hüttig's isotherm; this involves restriction to entirely two-dimensional clusters and the finite number $2n_s$ of adsorbed molecules for $p = p_s$.



——, Experimental; – – – –, Hüttig; . . . . , Brunauer–Emmett–Teller; —·—·, cluster-isotherm

Adsorption isotherms for the system H_2O–$BaSO_4$ at 273° K.

The agreement between formula (2) and experiment is found to be very satisfactory. This can be seen from the accompanying graph, which is characteristic of a large number of cases. The parameter s, which is 5 in this case, has been found to assume values between 2 and 12 in other systems and to increase with temperature.

Details of this work will be published elsewhere.

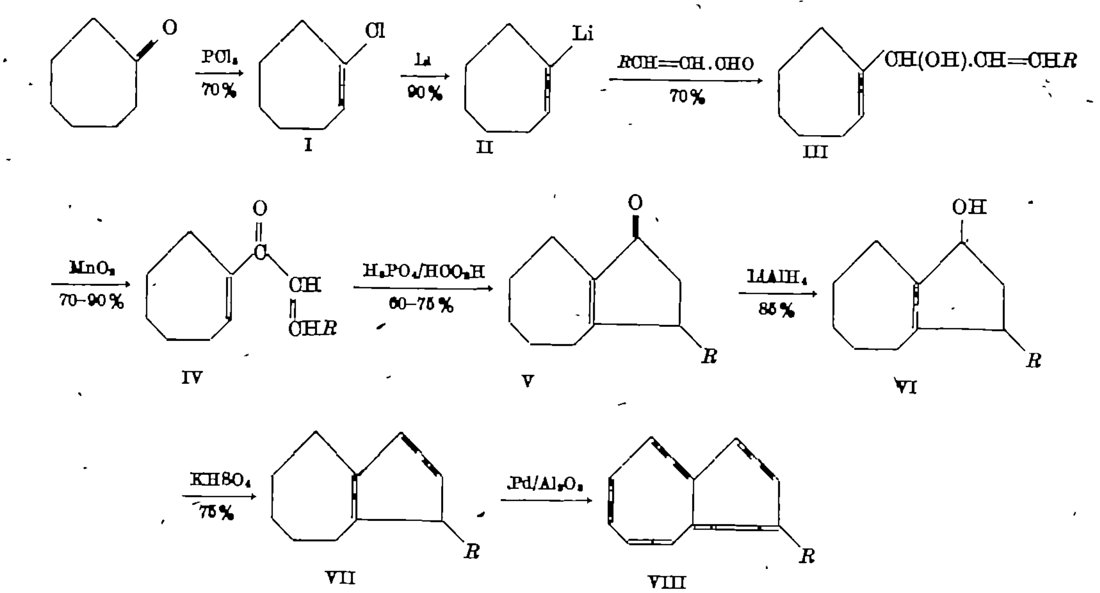
A New Route to Azulenes

Although several syntheses of azulene (VIII; R=H) and azulene derivatives have been described[1], investigations on the chemistry of this non-benzenoid aromatic system have been hampered by the fact that the procedures hitherto available do not readily lend themselves to the preparation of azulenes on more than a relatively small scale. We have recently developed a new synthesis, based on the method of alkenylation with lithium alkenyls[2], which offers some advantages in this respect.



The new synthesis is illustrated here for azulene itself and for 1-methylazulene. 1-Chloro*cyclo*heptene (I), prepared by treating *cyclo*heptanone with phosphorus pentachloride[3], is readily converted into 1-*cyclo*heptenyl lithium (II) by reaction with lithium metal in ether suspension[4]. The lithium alkenyl undergoes the usual addition reaction with acraldehyde or crotonaldehyde, to give the dialkenylcarbinols (III; R=H or Me)[4]. Oxidation of the latter with manganese dioxide in petrol suspension[5] affords the dialkenyl ketones (IV; R=H) (b.p. 61°/0·5 mm., n_D^{21} 1·5138; found: C, 80·4; H, 9·7; $C_{10}H_{14}O$ requires C, 80·0; H, 9·4 per cent), 2 : 4-dinitrophenylhydrazone (m.p. 198°), and (IV, R=Me) (b.p. 84°/0·4 mm., n_D^{25} 1·5166; found: C, 80·6; H, 10·1; $C_{11}H_{16}O$ requires C, 80·4; H, 9·8 per cent), 2 : 4-dinitrophenylhydrazone (α-form, m.p. 118°; β-form, m.p. 129°). Treatment of the ketones (IV) with a mixture of phosphoric and formic acids[6] at 90° resulted in smooth cyclization to the octahydroketoazulenes (V, R=H), $\lambda_{max.}$ 2410 (ε 12,300) and 2910 A. (ε 85) in ethanol; semicarbazone, m.p. 238° (reported[7,8] m.p. 238° and 235–236°) and (V, R=Me) (b.p. 77°/0·4 mm.; n_D^{20} 1·5118; $\lambda_{max.}$ 2440 (ε 9200) and 3000 A. (ε 65) in ethanol; found: C, 80·4; H, 9·8; $C_{11}H_{16}O$ requires C, 80·4; H, 9·8 per cent), 2 : 4-dinitrophenylhydrazone (m.p. 236°). Reduction of the octahydroketoazulenes with lithium aluminium hydride in ether at 0° gave the hydroxyoctahydroazulenes (VI, R=H) (b.p. 64°/0·1 mm., n_D^{18} 1·5132; found: C, 79·1; H, 10·9; $C_{10}H_{16}O$ requires C, 78·9; H, 10·6 per cent) and (VI, R=Me) (b.p. 80°/0·4 mm., n_D^{21} 1·5058; found: C, 79·5; H, 10·9; $C_{11}H_{18}O$ requires C, 79·5; H, 10·8 per cent), 3 : 5-dinitrobenzoate (m.p. 87°). Dehydration of the alcohols (VI) by distillation from potassium bisulphate and dehydrogenation of the resulting dienes (VII) with a palladium–alumina catalyst[9] afforded azulene (VIII, R=H) and 1-methylazulene (VIII, R=Me). The latter gave an *s*-trinitrobenzene adduct (m.p. 155°, undepressed on admixture with an authentic specimen kindly provided by Prof. Pl. A. Plattner[7]).

Other methods of effecting the last step are under investigation, and details of this work will be published elsewhere in due course.

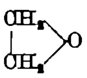
Some Trithiocarbonate Derivatives of Carbohydrates

Ethylene oxide (I) and its simple analogues react with carbon disulphide and potassium hydroxide in methyl alcoholic solution to give cyclic compounds, containing three atoms of sulphur, which are termed trithiocarbonates. Culvenor, Davies and Pausacker[1] described the transformation of ethylene oxide into ethylene trithiocarbonate (II), and of *cyclo*hexene oxide into *cyclo*hexene trithiocarbonate. Furthermore, although this transformation has not yet been carried out, these compounds should readily undergo reductive desulphurization



I

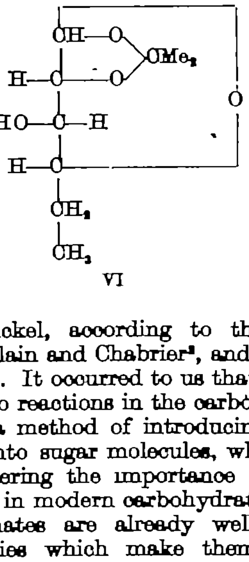
V



VI

with Raney nickel, according to the method of Bougault, Cattelain and Chabrier[2], and afford ethane and *cyclo*hexane. It occurred to us that the exploitation of these two reactions in the carbohydrate series might lead to a method of introducing two vicinal deoxy groups into sugar molecules, which might be of value considering the importance now assumed by deoxysugars in modern carbohydrate chemistry.

Sugar carbonates are already well known and possess properties which make them particularly useful in synthetic work, because the carbonate group is stable to mildly acidic conditions but labile to alkaline reagents. Haworth and Porter[3] prepared glucofuranose 5 : 6-carbonate (III) in 1929 and used it to prepare crystalline glucofuranoside derivatives. It is anticipated that trithiocarbonates may also find uses in synthetic sugar chemistry, not only as protective groups but also as a means whereby thiol groups may be introduced into sugar molecules.

We have now found that three ethylene oxide derivatives of carbohydrates readily yield trithiocarbonate derivatives, and that these undergo smooth reductive desulphurization to furnish the corresponding dideoxy compounds.

1 : 2 - *iso*Propylidene 5 : 6 - anhydroglucofuranose (IV), on treatment with carbon disulphide and potassium hydroxide in boiling methyl alcohol, furnished 1 : 2-*iso*propylidene 5 : 6-dideoxyglucofuranose trithiocarbonate (V), melting point 179·5–180·5° (found: C, 40·8; H, 4·52; S, 32·3; $C_{10}H_{14}O_4S_3$ requires C, 40·8; H, 4·76; S, 32·6 per cent). This, on reductive desulphurization with Raney nickel in boiling ethyl alcohol, afforded 1 : 2-*iso*propylidene 5 : 6-dideoxyglucofuranose (VI), melting point 78°, $[\alpha]_D^{11}$ $-31·4°$ (in chloroform) (found: C, 57·4; H, 8·5. $C_9H_{16}O_4$ requires C, 57·4; H, 8·5 per cent). 1 : 3-2 : 4-Diethylidene 5 : 6-anhydrosorbitol and 1 : 2-3 : 4-di-*iso*propylidene 5 : 6-anhydromannitol serve as examples of hexitol derivatives which may participate in this reaction. The sorbitol derivative gave rise to 1 : 3-2 : 4-diethylidene 5 : 6-dideoxysorbitol 5 : 6-trithiocarbonate as yellow needles of melting point 182–183·5° (found: C, 43·0; H, 5·37; S, 30·7; $C_{11}H_{16}O_4S_3$ requires C, 42·8; H, 5·2; S, 31·2 per cent), which was smoothly transformed, by treatment with Raney nickel, into 1 : 3-2 : 4-diethylidene 5 : 6-dideoxysorbitol, melting point 84·5–85·5°. This was clearly identical with the compound, melting point 85–86°, prepared by Bladon and Owen[4], by the treatment of 5 : 6-ditoluene-*p*-sulphonyl 1 : 3-2 : 4-diethylidene sorbitol with sodium iodide followed by hydrogenation of the corresponding 5 : 6-sorbitoleen produced. The mannitol anhydride afforded 1 : 2-3 : 4-di-*iso*propylidene 5 : 6-dideoxymannitol 5 : 6-trithiocarbonate, melting point 95–96° (found: C, 46·5; H, 6·04; S, 28·8; $C_{13}H_{20}O_4S_3$ requires C, 46·4; H, 5·95; S, 28·6 per cent), which, on reductive desulphurization gave 1 : 2-3 : 4-di-*iso*propylidene 5 : 6-dideoxymannitol as a liquid distilling at 90° (bath temperature)/0·05 mm. and showing $[\alpha]_D^{18}$ $+11·5°$ (in alcohol) (found: C, 62·9; H, 9·2; $C_{12}H_{22}O_4$ requires C, 62·6; H, 9·6 per cent).

All three trithiocarbonate derivatives were beautifully crystalline solids of bright yellow colour showing a strong absorption band in the ultra-violet region of the spectrum at λ 3160 A. (ε max. 13,500–15,000).

Tetrabromothiophene from 2-Bromothiophene by means of Sodium Acetylide in Liquid Ammonia

In the course of our investigations on acetylenic compounds in the thiophene series[1], it was desired to synthesize 2-thienylacetylene directly from 2-bromothiophene and 2-chlorothiophene by means of sodium acetylide in liquid ammonia. Although it is known that arylations via this method are unsuccessful when applied to halides in the benzene series[2a,b], no experiments are recorded in the literature with heterocyclic compounds. In view of the greater reactivity of the thiophene nucleus, it appeared worth while to attempt this reaction.

2-Bromothiophene was prepared according to an earlier description[3], the sodium acetylide by known methods[2a,b], and the 2-chlorothiophene used was a commercial product.

While 2-chlorothiophene did not react and the starting material was recovered quantitatively, 2-bromothiophene reacted vigorously. To the prepared sodium acetylide in liquid ammonia the calculated amount of 2-bromothiophene was added by drops. The reaction mixture was stirred for four hours and hydrolysed with water. When sodium acetylide was prepared without using a catalyst (hydrated iron nitrate), the reaction mixture turned from colourless to light brown and finally, after hydrolysis of the mixture, to black. There was also present a large amount of free carbon. Under analogous conditions, when employing 2-chlorothiophene, no free carbon was noticed. After isolation of the reaction product with ether, there resulted a crystalline substance and we regained some starting material. From 50 gm. (0·32 mole) of 2-bromothiophene we obtained 10–14 gm. of the crystalline substance, 13 gm. (0·08 mole) of recovered 2-bromothiophene, and 2 gm. of a high-boiling oil, probably a mixture of di- and tri-bromothiophene. The yield of the crystalline substance was 35–45 per cent, depending on the method of preparation of the sodium acetylide. The yield was greater when the sodium acetylide was prepared via sodium amide using an iron nitrate catalyst.

The substance, recrystallized from dilute ethanol, gave white needles melting at 114° C. The analysis gave the following results: calculated for C_4Br_4S: C, 12·02; Br, 80·00; S, 8·04; found: C, 12·31; Br, 80·25; S, 8·44. The molecular weight determined by the Rast method was 380 ± 12. The product was identified as tetrabromothiophene, in that it did not depress the melting point on admixture with an authentic specimen prepared according to the method of Volhard and Erdmann[4].

Further investigations on this type of reaction are being carried out.

Urea as a Solvent

Although urea is an inexpensive laboratory chemical, its solvent properties do not appear to have been fully appreciated by chemists. Nevertheless, it may well prove to be one of the most versatile solvents known. Maintained at its melting point of 132° (conveniently done, if so desired, by refluxing with xylene with which it is immiscible) its decomposition is very slow. It then combines the solvent properties of water with that of alcohols.

Of approximately a hundred and twenty common inorganic chemicals, the only water-soluble compound which could not be dissolved in urea was sodium silicate. On the other hand, iodine proved to be very soluble.

In general, ions in urea solution possess their familiar colours, save that cobalt solutions are blue. Powerful oxidizing and reducing agents are, of course, decomposed; nevertheless, alkali metal chromates, dichromates and ferricyanides are surprisingly stable, the last-named much more so than in formamide solution.

Common inorganic precipitation reactions can be carried out in urea solution; precipitates of sulphur, copper, mercury, silver, mercurous chloride, mercuric iodide, barium sulphate, thallium iodide, silver chloride, bromide and iodide, silver chromate, magnesium and barium carbonates, copper ferrocyanide, heavy-metal sulphides, nickel dimethylglyoxime, etc., were readily obtained.

Urea dissolves methyl orange, phenolphthalein and litmus readily—the colouring matter is rapidly dissolved from litmus paper, giving a blue or red solution depending upon the acidity. Sodium carbonate is easily soluble and can be titrated with such acids as sulphuric, sulphamic or oxalic. With phenolphthalein, sodium carbonate gives a deep red solution below 140°; at 150° the colour is discharged but returns reversibly on cooling. Ammonium salts of strong acids give strongly acid solutions when hot which reversibly become alkaline on cooling. Alkali hydroxides are soluble but produce carbonate fairly rapidly. Acid solutions attack metals, evolving hydrogen.

Urea proved an excellent solvent for all save a small number of common organic chemicals. Among those with low molecular weights only hydrocarbons were insoluble. Nitro, amino and carboxy groups confer increasing solubility in the order given. Hydroxy compounds, ketones, esters, anilides, amino-acids, substituted hydrazines, etc., are readily soluble and decomposition is rare. Often the organic compound is miscible with molten urea in all proportions. Gluten, dextrin, sodium alginate, gum arabic, soap, etc., dissolve readily.

In the laboratory, urea is a valuable tool for dissolving sparingly soluble compounds. (1) A 5 per cent solution of N-phenylanthranilic acid in molten urea is cooled and powdered. For use as an oxidation-reduction indicator, 0·5 gm. of the solid is added to a solution, when the urea instantly dissolves, leaving the indicator as a finely divided suspension in the liquid. (2) So-called 'soluble' starch dissolves in urea to give a highly viscous clear solution. If a 5 per cent solution is cooled and powdered, the product is ideal for use in titrations involving iodine. It dissolves almost instantly to give a clear colourless solution which is still highly sensitive to iodine, giving the familiar blue colour.

A Rapid Method for the Determination of Nucleic Acid Components by Paper Partition Chromatography

Methods for the analysis of small amounts of nucleic acids and their components by paper partition chromatography have been described by Vischer and Chargaff[1] and Chargaff *et al.*[2]. Photographic methods for their identification on paper have also been used[3,4], based on the specific absorption in the ultra-violet range of the spectrum of the nucleic acid components. The present communication describes a simple and sensitive method for rapid analysis in routine work.

Hydrolysis. The purines, adenine and guanine, and the pyrimidine nucleotides, cytidylic acids and uridylic acids, were obtained by acid hydrolysis of yeast nucleic acid (1 hr., 1 *N* hydrochloric acid, 100° C.).

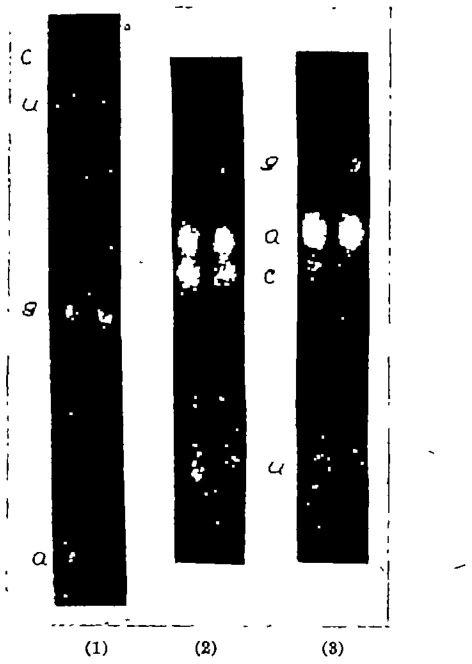
Separation. Spots containing 50–150 γ nucleic acid were prepared on filter paper (Munksell OB) by an Agla micropipette. Butanol was used as a solvent in the following two solutions: (*a*) *N*-butanol (4), dioxane (1) and distilled water (1), the spots on the paper being neutralized by gaseous ammonia; (*b*) *N*-butanol (4), diethylene glycol (1) and 1·5 *N* hydrochloric acid (1). Table 1 shows the R_F values found.

Table 1. R_F VALUES

	Solutions	
	a	*b*
Adenine	0·64	0·29
Guanine	0·37	0·18
Cytidylic acid	0 09	0·35
Uridylic acid	0·17	0 63

A suitable time for separation on paper strips 40 cm. long was found to be 18 hr. After drying the paper strips for two hours at 80–90° C., photography was carried out in the ultra-violet range.

Optical equipment. Monochromatic light of wavelength 257 μμ and 275 μμ was generated between rotating cadmium electrodes of an ultra-violet microscope constructed according to Köhler. A quartz condenser of numerical aperture 0·3 and a 6-mm. monochromat of numerical aperture 0·35 corrected for 257 μμ or 275 μμ (Cooke, Troughton and Simms) was used. 60 cm. from the exit pupil of the objective a drum was fastened to a stand, with its axis perpendicular to the incident light and within the homogeneous field of illumination. The drum is 13 cm. in diameter and 12 cm. wide, provided with a fold at the edges, and it is rotated by a crank. Paper strips 5–10 cm. wide were photographed against a blue-sensitive photographic paper of similar width. Paper and film were braced by two strips of brass, the distance between which could be varied. Thus, paper up to 40 cm. in length could be photographed continuously. Uniform exposure was obtained by rotation of the drum for 60 sec. at 257 μμ and for 30 sec. at 275 μμ.



Paper strips 5 cm. broad photographed in the ultra-violet (1) With butanol–dioxane–distilled water as solvent at 257 μμ, (2) and (3) with butanol–diethyleneglycol-hydrochloric acid at 275 μμ and at 257 μμ. In both instances 65 γ yeast-nucleic acid was subjected to separation *a*, *g*, *c* and *u* refer to adenine, guanine, cytidylic acid and uridylic acid respectively. Note increase in sensitivity at 275 μμ

Results. Photographs of some chromatograms are reproduced in the accompanying figure. The sensitivity of the method for purines and pyrimidines in γ per cm.[2] can be seen from Table 2.

Table 2

Adenine	0·35
Guanine	0·55
Cytosine	0 75
Uracil	0 45
Thymine	0 60

By using the cadmium band at 275 μμ the value for cytosine can be halved.

Identification of Sulphonamides on Paper Chromatograms

THE recent communication on this subject by R. Robinson[1] has prompted me to record some observations made about two years ago on this subject.

Butanol – acetic acid solvent was found the most satisfactory of many solvents tried, being prepared by mixing *n*-butanol, acetic acid and water in proportions 50–15–35 by volume. The mixture is homogeneous and very slightly under-saturated with water at room temperature, it is easily prepared and gives reproducible R_F values which are almost identical with those obtained with the equilibrated solvent suggested by Partridge in 1948.

R_F-values found range from 0·55 (sulphaguanidine) to 0·85 (sulphamerazine). Some good separations are obtained; for example, the three components of sulphatriad can be demonstrated in the urine of a patient on treatment with this drug.

Detection of the sulphonamide spots makes use of the diazo- and coupling reaction carried out in alcoholic solution to minimize spreading of the spots. Nitrous acid solution is sprayed on the dried paper, followed after one minute, by a 1 per cent solution of dimethyl-α-naphthylamine or similar coupling reagent. The sulphonamides show as red or pink spots of the azo colour, one microgram being readily detected.

No spreading of the spots occurs and quantitative measurements have been carried out quite successfully using the method described by Fisher *et al.*[2].

The nitrous acid solution is prepared as follows: 0·1 gm. of sodium nitrite in 1 ml. of water is shaken with 10 ml. of *n*-butanol, and 0·3 ml. concentrated hydrochloric acid added with shaking. The mixture is allowed to stand for a few minutes before use; solid sodium chloride may separate. The solution is stable for several days.

Phenolases in the Echinoid, *Diadema antillarum* Philippi

Diadema antillarum possesses an abundant black pigment which shows the chemical and histochemical properties of melanin, and is concentrated in epidermal chromatophores[1]. In view of much evidence from other forms of a relationship between the occurrence of melanin and phenolases, evidence of such enzymes in *Diadema* was sought.

Cœlomic fluid removed from the animal forms a colourless slimy clot of aggregated cœlomic amœbocytes, which rapidly changes to red, and then, as in '*Thyone*'[2], slowly becomes brown or black. In *Diadema*, the process involves oxidation, since it is hastened by aeration and prevented if the fluid is exposed in nitrogen. The pigment produced has the characteristics of melanin.

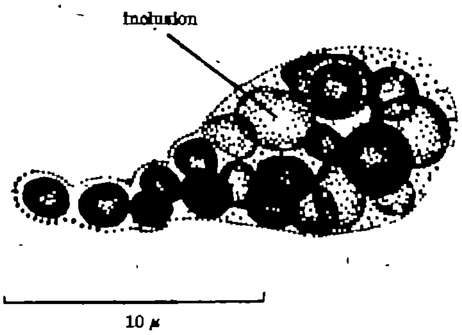
Darkening is inhibited by boiling and by 0·0003 *M* potassium cyanide, and thus appears to be an enzymatic process involving oxidases. Phenolases are indicated by the character of the colour change, and the production of coloured oxidation products by the action of the cœlomic fluid on phenolic substrates such as 1-tyrosine, dihydroxyphenylalanine, pyrocatechol, *p*-amino phenol, quinol and pyrogallol, buffered within the *p*H range 6·5–7·4. The reactions are accelerated by detergents. As reported by Pugh and Raper[3] for mealworm phenolases, the enzyme system does not act on quinol at *p*H 7·0 unless the solution is dilute (0·0002 *M* in *Diadema*).

Other features of these colour reactions indicating participation of phenolases are activation by ultra-violet light and inhibition by 0·0002 *M* potassium cyanide and hydrogen sulphide. 3 *M* Ethanol and 4 *M* methanol are usually inhibitory, though not invariably so. It is highly significant that darkening of the clot in cœlomic fluid is similarly affected by these factors, and further, it is usually, but not always, inhibited by *p*-benzyl-hydroquinone ('agarite alba').

The enzymes are not part of the cytochrome–cytochrome oxidase system, since they are soluble in water, unaffected by 0·002 *M* sodium azide at *p*H 7·3 and only slightly affected by acetone.

There is thus evidence of both monophenolase and polyphenolase activity in the cœlomic fluid.

Both activities are shown by the clot alone, and both are markedly increased when it is removed from the fluid and later replaced in the same fluid which has been boiled and cooled. This indicates the presence of a heat-labile inhibitory factor in the fluid, which could be associated with a system of low oxidation–reduction potential, for the potential of the fluid is lower than that of the amœbocytes.



Living amœbocyte from a freshly formed clot of cœlomic fluid showing spheroidal inclusions

Darkening of the clot on exposure to air is due to blackening of spheroidal or discoidal cytoplasmic inclusions in the amœbocytes (see diagram), which occurs whether the inclusions be *in situ*, or free, following breakdown of the amœbocytes after centrifuging and shaking. They therefore appear to play an essential part in pigment production, embodying enzyme, substrate, or both. The fact that they also blacken after intra-cœlomic injection of dihydroxyl-phenylalanine in sea water affords further indication that they contain the enzyme system. A varying proportion of the inclusions are bright red; but the significance of the red pigment in relation to their subsequent blackening is obscure. Should it transpire to be an echinochrome, it may prove of importance in view of the participation of these and similar compounds in reversible oxidation–reduction systems (Cannan[4]), and the importance of such systems in regulating melanogenesis[5].

A full account of the investigation will be published elsewhere.

Potentiation by Adrenocorticotrophin of the Diabetogenic Action of Growth-Hormone Preparations

THE adrenocorticotrophic hormone is not a potent diabetogenic agent in the intact cat[1], in contrast to growth hormone. Its influence on the diabetogenic activity of growth-hormone preparations in the intact cat has now been studied, as briefly reported elsewhere[2].

The growth-hormone preparations were derived from ox anterior pituitary glands, and included crude extracts and purified products[3]. The growth-hormone content of the former was assayed in adult female rats[4]. The adrenocorticotrophic hormone preparation employed in the present experiments was derived from pig pituitary glands, and had a potency 2·5 times that of the Armour standard (ascorbic acid depletion). Both preparations were given subcutaneously, at different sites, to intact adult male cats fed on a meat diet, the intake of which varied little from day to day[5]. In each test, treatment was continued until a glucose excretion exceeding 5 gm. in 24 hr. ('5-gm. response'[5]) had been induced. The growth-hormone preparation was given once daily, and the other preparation usually three times daily (during eight hours).

In a given cat there is an inverse relationship between the dose of a diabetogenic preparation and the period of treatment required to induce the '5-gm. response'[5]. Thus, in control experiments with a crude extract in cat 231 (tests 1 and 2, Fig. 1), a daily dose of 6 mgm. (expressed as growth hormone) was effective in three days, and one of 2 mgm. (trebled after six days) was effective only after eight days of treatment. When, however, the growth-hormone preparation was given at a daily dose of 2 mgm. in conjunction with adrenocorticotrophic hormone, the response was obtained in only three days. Since the subsequent control test showed that the sensitivity of the cat to the growth-hormone preparation alone had not changed, it was concluded that the adrenocorticotrophic hormone had potentiated its diabetogenic action. Tests 5 and 6, in conjunction with the preceding tests, indicate that adrenocorticotrophic hormone given at a reduced dose, only once daily, still had some potentiating action.

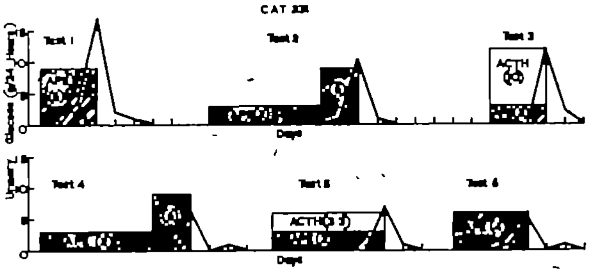

Fig 1

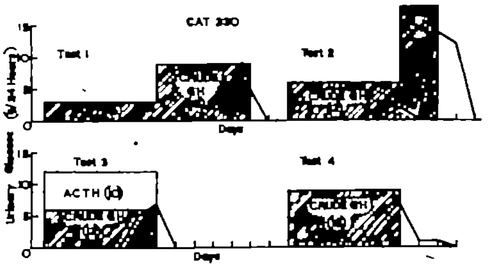

Fig 2

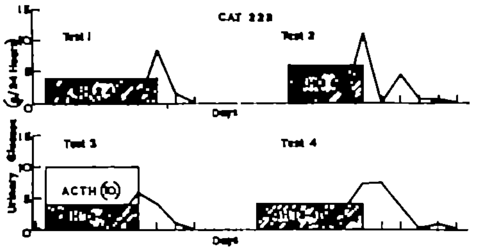

Fig 3

Potentiation experiments using adrenocorticotrophic hormone (*ACTH*) with: (1) crude anterior pituitary extract (*APE*) in cat 231; (2) a crude growth-hormone preparation (= crude *A* fraction of Wilhelmi *et al.*[3]) in cat 230; (3) a purified growth-hormone preparation in cat 222. Period of treatment denoted by rectangle, the height of which is, for each cat, proportional to the daily dose (also indicated numerically). Doses expressed as mgm. of growth hormone (*GH*) or, in the case of adrenocorticotrophic hormone, as mgm. of Armour standard

In cat 230 (Fig. 2), with a crude growth-hormone preparation, 12 mgm. given with adrenocorticotrophic hormone (test 3) was as effective as 18 mgm. given without the latter with respect to the period of treatment required to induce the response. A smaller, but probably significant, potentiating action of adrenocorticotrophic hormone was observed in cat 222 (Fig. 3) with a purified growth-hormone preparation. In this experiment, 2·4 mgm. of growth hormone given with adrenocorticotrophic hormone (test 3) was more effective than 2·4 mgm., but less effective than 3·6 mgm., of growth hormone given alone.

It is concluded that the diabetogenic action of growth-hormone preparations in the intact cat may be augmented by adrenocorticotrophic hormone given simultaneously. While the investigation was in progress, Engel and co-workers[6] briefly reported that growth hormone is diabetogenic in the force-fed rat if adrenocorticotrophic hormone is given simultaneously, although growth hormone alone is not a potent diabetogenic agent in the rat.

My experiments were performed during the tenure of a Beit Memorial fellowship. The costs were largely defrayed by a grant from the Medical Research Council to Prof. F. G. Young, to whom I am indebted for his interest and encouragement. Thanks are expressed to Drs. I. M. Bunding, E. E. Hays and J. R. Mote, of Armour and Co., Chicago, for providing adrenocorticotrophic-hormone preparations, and to Prof. A. E. Wilhelmi for advice on the preparation of growth hormone. For technical assistance, thanks are expressed in particular to Mr. M. Snowdon.

Low Toxicity of the Diphtherial Culture Filtrate and its Relation to the Absence of Tyrosine in the Medium

I HAVE already shown[1] that the diphtherial culture filtrate harvested from the chemically defined media (A.M.C. and A.M.T. medium) containing two (asparagine, DL-methionine) or three amino-acids (asparagine, DL-methionine and L-cystin) as a nitrogen source had a very low toxicity for guinea pigs, while it showed a high degree of flocculation units.

While searching for the causes of this phenomenon, it has been observed that the presence of tyrosine in culture medium plays an important part in controlling the toxicity of the diphtheria toxin produced. Typical results are given in Table 1. It will be seen that the median lethal dose per flocculation unit of the culture filtrate harvested from the medium containing tyrosine is about 35–100, whereas it is only 3–18 when tyrosine is absent.

Table 1. EFFECT OF THE PRESENCE OF TYROSINE IN MEDIUM ON THE TOXICITY OF THE CULTURE FILTRATE OF *C. diphtheriae*

Tyrosine (0·1 gm./l. of medium)	Exp. No.	Toxin content (Lf./ml.)	Toxicity (M.L.D.)	M.L.D./Lf.
Absent	1	20	100	5
	2	30	100	3
	3	28	100	4
	4	56	1,000	18
	5	60	500	8
	6	90	500	5
Present	1	10	1,000	100
	2	20	1,500	75
	3	17	1,500	88
	4	28	1,000	35
	5	40	2,000	50
	6	45	2,000	45

The A.M.T. medium used throughout this work was prepared by my method[2] with careful adjustment of starting pH (7·0) and iron concentration (1–2γ/30 ml. of medium), and its composition was as shown in Table 2. Tyrosine dissolved in phosphate buffer (pH 7·0) was added to the medium just before inoculation (0·1 gm./litre of medium).

Table 2

Asparagine	5·0 gm.
DL-Methionine	0·3 gm.
Sod. thioglycollate	0·5 gm.
Pot. dihyd. phosphate	5·0 gm.
Calcium chloride	1 0 gm.
Sodium chloride	4·0 gm.
Maltose	12·5 gm.
Sod. lactate	1·75 gm.
Mueller's II solution (ref. 3)	2·0 ml.
Aqua redest.	1,000 ml.

After inoculation with the pellicle from a four-day old culture of a sub-strain (adapted to the synthetic medium mentioned above) of *P.W.* No. 8 (Toronto Harvard) strain and eight or nine days incubation at 33–35° C., flocculation units and median lethal dose for guinea pigs (250–260 gm.) belonging to a vigorous stock were determined.

In 1943, Seki[4] described his finding that the removal of the crystalline (tyrosine) formed during the preparation of casein acid-hydrolysate tends to decrease the toxin content (from the estimation of median lethal dose) of the culture filtrate harvested from the casein hydrolysate medium; and Linggood and Woiwod have recently shown that tyrosine is present in toxin but not in toxoid hydrolysate of diphtheria on two-dimensional paper chromatograms[5]. Therefore, the possibility of an intimate connexion between the toxic group of diphtheria toxin and tyrosine present in the culture medium may be supposed, but the intrinsic significance of tyrosine is not yet clear. Further work to find the actual mechanism involved is now in progress. This will be published in detail later.

Factor *Rb* Activity in Human Plasma

FACTOR *Rb* is a protein-like, heat-labile requirement of the nematode *Rhabditis briggsae* Dougherty and Nigon, 1949, for growth and reproduction under axenic conditions[1,2]; chick embryo and mammalian liver have been shown to be good sources of it, and some activity has previously been noted in human whole blood and plasma[2].

It is of interest to report now that, when properly supplemented, human plasma has been shown, by recent work, to be a good source of factor *Rb*. The plasma used was obtained through the courtesy of Dr. Karol A. Hok, of the Cutter Laboratories, Berkeley; it was irradiated, lyophilized material, pooled from many donors and with approximately 0·4 per cent sodium citrate included as an anticoagulant. Water was added to restore the original volume, and the liquid was sterilized by Seitz filtration. Part of the sterile product was dialysed under sterile conditions against three changes of a large volume of distilled water. Both the dialysed and undialysed material were tested as sources of factor *Rb*. This was done by adding to each of a series of *Neurospora* growth-tubes 1 ml. of one of the plasma preparations and 1 ml. of an autoclaved liver preparation made by homogenizing horse liver with an equal weight of distilled water, centrifuging the product at 20,000 *g*, autoclaving the supernatant fluid, homogenizing the product, recentrifuging at 20,000 *g*, and sterilizing the clear supernatant by passing it through a Seitz filter.

The foregoing media have uniformly supported the production of vigorous cultures inoculated with a few dozen tiny larvæ. These results are in contrast to limited growth (maturation without successful reproduction) of larvæ placed in plasma supplemented with certain known ingredients[2].

The newer results are particularly significant for the development of a defined medium for *R. briggsae*, because the protein constitution of human plasma is the best known of any complex biological material[3]. It will now become possible to test the plasma protein fractions already available and probably to determine in which of these the factor *Rb* activity resides. This has a great advantage over extending the tedious fractionation of liver protein already carried out[2,4]. It may supply a rationale for the failure of peptic digestion to release factor *Rb* activity in non-protein form from liver protein[5].

The foregoing preliminary results are reported at this time by reason of the fact that further investigations on plasma protein will probably be delayed for more than half a year by projected travel abroad.

Note added in proof. My student, Douglas F. Keith, has recently been able to show that factor *Rb* activity is apparently confined to those plasma fractions rich in β-globulins (fractions III and IV). He is now testing subfractions of these fractions, particularly as supplemented only by known ingredients (that is, vitamins, salts, etc.).

The Rabbit Lumbrical: a New Isolated Mammalian Nerve–Muscle Preparation

THE rat diaphragm phrenic nerve preparation[1] enabled mammalian muscle to be studied under precise conditions of drug and ion concentration, but is insensitive to decamethonium (*C*10). The object of this communication is to describe a new isolated mammalian nerve–muscle preparation which does not suffer from this disadvantage. Several muscles in the feet of rabbits and cats are suitable; but the medial lumbrical of the rabbit's hind foot has been found most satisfactory. It is usually about 18 mm. long and 1 mm. in diameter under physiological tension.

A rabbit is killed and bled, and the skin removed from one hind leg. It is very adherent on the plantar surface of the foot and must be carefully removed, since the nerve is immediately beneath it.

The long, very fine tendon of insertion of the medial lumbrical which passes around the medial side of the second digit is secured by a piece of silk and cut distally. Next the plantaris tendon passing to the second digit is separated and removed, allowing the lateral side of the muscle to be freed back to its origin from the junction of the medial two tendons of flexor digitorum longus.

The tibial nerve is dissected distally to the point where it splits into a sheaf of branches which turn diagonally to cross the plantaris tendons, and gently retracted laterally, to allow the medial plantaris tendon to be carefully separated and removed. The medial side of the muscle can now be freed up to its origin, and the part of the tendon from which the muscle arises is cut out with the muscle attached. This lumbrical is occasionally vestigial or absent, and variations in the nerve supply sometimes occur.

Directly and indirectly elicited contractions are equal in height provided the nerve is undamaged, although there may be some degree of temporary initial block, presumably due to anoxia during the dissection.

Using a weight-loaded lever designed to act ballistically, records of the order of 8 cm. in height are regularly obtained.

A gas mixture consisting of 95 per cent oxygen and 5 per cent carbon dioxide is used, and the temperature is maintained at 39° C. The preparation is sensitive to both *d*-tubocurarine and decamethonium. The reaction to decamethonium and sensitivity to both drugs are, however, very dependent on temperature and ionic concentration. At a stimulus-rate of about eight a minute, the preparation continues to contract without reduction in height or neuromuscular block for prolonged periods of time.

This investigation was supported by a grant from the Research Committee of the University of California Medical School, San Francisco.

Selenium Toxicity associated with an Irish Soil Series

For a number of years a disorder in livestock has set a considerable farming problem in a district in County Limerick. In horses, this disorder in its severe form is shown by the loss of hair from mane and tail, with alteration in the growth, and eventually loss, of hooves. Horses affected in this way 'go down', while the less severe form of this condition is reflected in hoof deformation.

In cattle there is also alteration in the growth of hooves, with eventually the sloughing off of the old hooves and in some cases loss of the tail. The cattle thus affected show poor condition.

Due to loss and alteration of the growth of hooves, affected cattle find difficulty in moving about and in some cases assume a kneeling position when grazing.

An examination of soil and herbage samples has revealed nothing unusual with regard to major or minor elements, while blood samples analysed by Dr. O'Moore of the Veterinary Research Laboratory showed normal levels of sugar, phosphorus, calcium, magnesium and copper. Due to the similarity of this condition to that described by American workers[1,2] as typical of selenium toxicity, soil and herbage samples were examined for selenium content by the method of Dr. W. O. Robinson[3], whose advice[4] we gratefully acknowledge.

These analyses have shown that the selenium content of soil from affected fields varies between 30 and 324 p.p.m., whereas samples from immediately adjoining healthy soils gave values of less than 2 p.p.m. The selenium content of mixed herbage samples from affected areas gave values varying from 150 to 500 p.p.m., the latter figure being obtained from the soil showing the highest selenium content. Analyses of herbage samples from immediately adjoining non-affected fields gave values less than 1 p.p.m. By comparison with American figures for highly selenized areas, the selenium level of soils reported here is extremely high, while that for herbage is well above the limit of 5 p.p.m. stipulated as being marginal for toxicity, especially when it is considered that the analyses were on ordinary mixed-herbage samples. There would seem to be no doubt, therefore, that this condition is due to selenium toxicity.

The soils affected are low-lying valley soils in a glaciated area where the underlying rock strata consist of Upper Carboniferous Limestone. They are dark grey fine sandy loams to medium loams with the organic carbon content varying from 5 to 15 per cent and ranging in reaction from slightly acid to alkaline. In general, drainage is somewhat impeded and manganese deficiency in cereals is a problem on some of these soils. Rainfall at 40 in. a year is moderately high. From this description it can be seen that the affected soils differ considerably from those described for seleniferous areas in the United States. The normal soils at higher elevation in this area are brown to grey-brown fine sandy loams to medium loams, quite fertile, and from the data so far available do not appear to have been selenized.

There is evidence to suggest that the formation of affected soils has been considerably influenced by wash from Yoredale Beds (Avonian shales) which lie immediately to the west of the affected area. From Geological Survey data available, it would appear that these beds contain considerable deposits of iron pyrites, a circumstance of importance when explaining the presence of selenium, as from the American work it would appear that pyritiferous shales may be rich sources of selenium.

Preliminary botanical examinations carried out have failed to reveal anything unusual in the composition of the herbage, especially in relation to the occurrence of selenium accumulators, of the pasture swards of affected areas.

Experimental work on a field- and laboratory-scale is proceeding, and the results will be published elsewhere in due course.

Heat Tolerance in European Breeds of Cattle Exposed to High Environmental Temperatures

Messrs. A. L. Badreldin, M. M. Oloufa and M. Abdel Ghany have reported observations on heat tolerance of cattle at Giza (*Nature*, 167, 856; 1951).

In the Singapore Dairy Farm, where more than six hundred head of Ayrshire, Holstein and Shorthorn cattle are kept as a commercial dairy herd, it has been possible to record rectal temperatures and respiration-rates of groups of fifty cows at hourly intervals for periods of seven days throughout the past nine months.

It is considered that the comparison of average air temperatures, etc., with average rectal temperatures and respiration-rate cannot produce information of much value. Clinical evidences of heat intolerance develop only when the rate of heat production within the body exceeds the rate at which heat can be lost to the exterior. The critical environmental temperature productive of a state of adverse heat exchange varies with the degree of air movement and ventilation. Further, the magnitude of the effects of exposure to high temperatures is dependent upon how far the critical temperature is exceeded and for how long.

In this herd, where normally air movement is negligible, rectal temperature commences to rise when that of the surrounding air reaches 78° F.; after one hour's exposure it averages 101·78° F. but after four hours exposure it averages 102·23° F. Two hours exposure to a byre temperature of 94° F. results in an increase to 104·45° F. If heat loss is assisted by hourly sprinkling with water and blast fans, byre temperatures of up to 89° F. cause no appreciable rise in rectal temperature.

Respiration-rate at all temperatures below 78° F. never exceeds 50 per minute; but above that temperature it rises progressively to 130 per minute at 94° F.

Accurate figures for pulse-rates of groups of cattle are extremely difficult to obtain, due to the disturbance necessitated during such mass examinations. However, indications are that pulse-rate is not depressed during heat stress unless it is severe, and that the converse is normally the rule.

It has been impossible to demonstrate any correlation between humidity and temperature regulation.

Preliminary findings on fifty-seven head of cattle would indicate that the chloride-level of the blood plasma rises during exposure to high environmental temperatures, tending to support the supposition that in European types of cattle water-loss is by evaporation through the lungs and diffusion through the skin rather than by direct sweating.

Singapore Dairy Farm,
Bukit Panjang, Singapore. Sept. 20.

Tone Sensation produced by Repetitive Trains of Auditory 'Click' Stimuli

It is well known that a sensation of continuous tone may be produced by presenting to the ear regularly repeated trains of sinusoidal waves, although each train may consist of only a few oscillations followed by a relatively long 'blank' period[1]. I have observed that a sensation of tone may arise by the presentation of trains of very short pulses, each pulse of duration of 0·20 m.sec., and each train consisting of two such pulses only. The pulse duration quoted is that measured on a cathode ray oscilloscope across the output of the amplifier, no suitable instrument being available to monitor the air pressure wave-form as produced by the loudspeaker. The pulses were derived from an electronic stimulator, and were locked to the time-base at predetermined times, each being independently adjustable. Hence, for each time-base two pulses were obtained, the separation of which in time could be varied from zero (coincidence) to 10 m.sec. The time-base repetition-rate could be varied from 10 to 100 per sec. Within this range, at any given rate of repetition, progressive separation of the pulses gave rise to a sensation of falling pitch, and approximation caused a rising pitch. At a separation of 1 m.sec., the sensation was that of a 1,000-cycle per sec. tone, as matched against a known frequency source; at a separation of 2 m.sec. the tone was 500 cycles per sec., at 4 m.sec. 250 cycles per sec., and so on. Since the tone sensation dependent on the pulse separation was heard against a background due to the frequency of repetition of each pulse (the time-base repetition-rate), only those derived tones of frequency considerably higher than the frequency of repetition could readily be detected and matched against the standard frequency source.

A simple theoretical interpretation of the phenomenon, based on the local resonator theory of auditory perception, may be offered. We assume that the first pulse of each pair, being of short time-duration compared with the tone sensation being studied, and having an abrupt initial rise, produces shock excitation of a wide band of resonators extending over the normal auditory spectrum. The second pulse arriving after an interval t will tend to augment the amplitude of resonators which have just completed integral numbers of complete cycles, that is, those of natural periods t, $t/2$, $t/3$, etc. Resonators of period $2t$ will be suppressed, having completed half a cycle and receiving the second pulse in antiphase. Resonators of other periods will be either only partially or not affected. Since of those which are selectively augmented (periods t, $t/2$, $t/3$, etc.) the decrement due to frictional losses will be progressively higher for the higher harmonics, the fundamental (t) and lower harmonics will predominate, giving a tone sensation identified as of period t (frequency $1/t$). The theory predicts that inversion (phase reversal) of the second pulse should result in selective augmentation of resonators of period $2t$, and suppression of those of period t. Preliminary experiments indicate that this occurs, in that the tone sensation falls in pitch by an octave when the second pulse is suddenly inverted. Since the tone sensation derived depends upon repetitive presentation of trains of two pulses (that is, a single presentation gives no sensation of the tone described), the observation seems to suggest a relatively slow decrement of the energy stored in a given resonator, which is not completely dissipated before the arrival of the next train in a sequence. This offers further support to the view of Pumphrey and Gold that the resonator elements of the cochlea possess a high Q factor. It is intended to modify the apparatus in order to study the phenomenon over a wider range of conditions.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 19

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Light Electrical Engineering and the Mechanical Engineer" (to be opened by Mr. T. E. Goldup).

Manchester Literary and Philosophical Society (in the Great Hall, College of Technology, Manchester), at 5.30 p.m.—Sir John Cockcroft, F.R.S.: "The Industrial Applications of Atomic Energy and its Products" (Joule Memorial Lecture).*

South-East London Technical College (at Lewisham Way, London, S.E.4), at 7 p.m.—Mr. P. Grodzinski: "Diamonds in Physical Instruments".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—M. André Liotard: "French Explorations in Antarctica".

Tuesday, November 20

Chadwick Public Lecture (at the Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Prof. William Holford: "The Health of Cities—Some Problems arising from Congestion and Overbuilding" (Bossom Gift Lecture).*

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. F. E. Zeuner: "Dating the Past". (Further Lectures on November 27, December 4 and 11.)

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Symposium on "Voluntary Sterilization" (Speakers: Dr. C. P. Blacker, Mrs. Moya Woodside, Mr. Cecil Binney).*

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. F. C. Williams, F.R.S., Dr T. Kilburn, Mr. G. C. Tootill, Mr. G. E. Thomas and Dr. A. A. Robinson: Papers on "Universal High-Speed Digital Computers"; Prof. F. C. Williams, F.R.S., and Mr. J. C. West: "The Position Synchronization of a Rotating Drum".

Society of Chemical Industry, Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. D. M. Newitt, F.R.S.: "Recent Trends in Chemical Engineering".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. A. W. Downie: "The Scientific Basis of Medicine, 13, Antibodies and Immunity to Virus Infection".* (Further Lectures on November 23, 27 and 29, December 4, 6 and 11.)

Manchester Geographical Society (at the Geographical Hall, 16 St. Mary's Parsonage, Manchester), at 6.30 p.m.—Major William Cross: "Reflexions upon Amazonian Exploration".

Textile Institute, Yorkshire Section (joint meeting with the West Riding Section of the Society of Dyers and Colourists, at the Midland Hotel, Bradford), at 7.15 p.m.—Dr. C. S. Whewell: "The Finishing of Cloths containing Wool and Synthetic Fibres".

Wednesday, November 21

Royal Microscopical Society (in the Great Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 2.30 p.m.—Exhibition of "How Industry is Using the Microscope".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Prof. L. Dudley Stamp: "The Reclamation of Abandoned Industrial Areas".

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Mr. W. P. Nicol: "Telecommunications in Aviation".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Scientific Papers.

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Mr. R. C. Mildner: "Developments in High Frequency Transmitter Cables".

Manchester Metallurgical Society (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Mr. W. Ramsden: "Spectrographic Analysis".

Society of Chemical Industry, Corrosion Group (joint meeting with the Birmingham and Midlands Section, in the University Mason Theatre, Edmund Street, Birmingham), at 6.30 p.m.—Mr. J. Welsh: "Corrosion in Gas Burning Appliances".

Oil and Colour Chemists' Association, London Section (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. F. Chapman: "Petroleum Chemicals and the Paint Industry".

Scientists for Peace (at the small Conway Hall, Red Lion Square, London, W.C.1), at 8 p.m.—Prof. J. B. S. Haldane, F.R.S., and Prof. C. F. Powell, F.R.S.: "The Threat to Science"

Wednesday, November 21—Thursday, November 22

Iron and Steel Institute (at 4 Grosvenor Gardens, London, S.W.1), at 10 a.m. each day.—Autumn Meeting.

Thursday, November 22

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. A. E. Smailes. "The Geographical Study of Towns".*

University of London (at the Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E.5), at 3 p.m.—Dr. W. Grey Walter: "The Relationship between the Electrical Activity of the Brain and Adaptive Behaviour".*

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. I. H. Burkill: "Habits of Man and the Origins of the Cultivated Plants of the Old World" (Hooker Lecture).

British Ornithologists' Union (at the Zoological Society of London, Regent's Park, London, N.W.8), at 5.30 p.m.—General Meeting; at 6 p.m.—Dr. A. J. Cain: "Selection and Evolution in the Parrot *Trichoglossus*".

Institution of Electrical Engineers, Utilization Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. W. Fordham Cooper: "Electrical Control of Dangerous Machinery and Processes, Part 3, Remote Supervisory Control".

Research Defence Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Sir Wilson Jameson, G.B.E. "Research and Administration—a Profitable Partnership?" (Twentieth Stephen Paget Memorial Lecture).

Royal Aeronautical Society (at St. Mary's College, Cheltenham), at 7.30 p.m.—Mr. A. N. Clifton: "Problems of Transonic Flight".

Textile Institute, Macclesfield, Leek and District Section (at Conlowe, Ltd., Canteen, Congleton), at 8 p.m.—Anne M. Buck: "History of Costume".

Friday, November 23

Library Association (at Chaucer House, Malet Street, London, W.C.1), at 11 a.m.—Discussion on the Library Association Working Party's Interim Report on "The Co-operative Provision of Books, Periodicals and related Material in Libraries".

British Society of Rheology (at the Institute of Physics, 47 Belgrave Square, London, S.W.1), at 2.30 p.m.—Mr. J. Evans: "The Strength of Soils in relation to the Performance of Cross-Country Vehicles"; Mr. P. Payne: "Some Problems in applying Soil Mechanics to the Action of Cultivation Implements".

Physical Society, Acoustics Group (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 4.30 p.m.—Discussion on "The Acoustics of the Royal Festival Hall" (to be opened by Mr. P. H. Parkin and Mr. W. A. Allen).

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion on "Earth Tides". (Speakers: Prof. Harold Jeffreys, F.R.S., Prof. R. Tomaschek, Dr. B. Baars and Dr. R. H. Corkan.)

Chemical Society, Newcastle and Durham Section (in the Chemistry Building, King's College, Newcastle-upon-Tyne), at 5.30 p.m.—Prof. R. P. Linstead, F.R.S.: "The Transfer of Hydrogen between Organic Compounds" (Bedson Club Lecture). (All Fellows are invited.)

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. Llewellyn Young: "The Control of Boilers Fired by Solid Fuels in Suspension".

Manchester Statistical Society, Statistical Methods Study Group (at the Albert Hall, Peter Street, Manchester), at 5.30 p.m.—Mr. G. H. Goode: "Technical Problems in calculating the Retail Price Index Number".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. A. A. Miles: "The Scientific Basis of Medicine, 14, Bacterial Aspects of Immunity".* (Further Lectures on November 27 and 29, December 4, 6 and 11.)

Geographical Association, Manchester Branch (in the Geography Room, Central High School for Boys, Whitworth Street, Manchester), at 6 p.m.—Mr. N. G. Fisher: "The Influence of Geography on Foreign Policy" (Presidential Address).

North-East Coast Institution of Engineers and Shipbuilders (at the Mining Institute, Neville Hall, Newcastle-upon-Tyne), at 6.15 p.m.—Dr. J. H. Richards: "An Analysis of Ship Vibration using Basic Functions".

Television Society (at the Cinematograph Exhibitors' Association, 164 Shaftesbury Avenue, London, W.C.2), at 7 p.m.—Mr. K. J. Easton: "Television Distribution by Wire".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. J. A. Ratcliffe, F.R.S.. "Radio-Astronomy".

Saturday, November 24

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Sir Richard Winstedt: "The Malay Races down the Centuries".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned.

Assistant Lecturer in Metallurgy, and an Assistant Lecturer in Physics, at Rotherham Technical College—The Director of Education, Education Offices, Rotherham (November 24).

Experimental Officer, Grade III, in the Long Range Weapons Establishment, Adelaide, to be responsible to a Senior Scientific Officer for the work of a team engaged in the application of photo and cine theodolites, instrument recording cameras and other special cameras, to ballistics and other aerodynamic problems—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (November 24).

Head of the Textile Department, Bolton Technical College—The Chief Education Officer, Education Offices, Nelson Square, Bolton (November 24).

DEPUTY FISHERIES AND POLLUTION OFFICER—The Clerk to the Devon River Board, The Castle, Exeter (November 30).

SENIOR LECTURER IN CIVIL ENGINEERING (Structures) at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 7).

SCIENTIST, Grade II (with a good university honours degree or equivalent in chemistry or physics, chemical engineering or fuel technology) on the staff of the Director of Scientific Control at London headquarters—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, endorsed TT/393 (December 8).

SCIENTISTS, Grade III (with a good honours degree, or equivalent, in science, mathematics or engineering) for operational research posts in the Field Investigation Group of the Directorate of Scientific Control—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/395 (December 8).

STATISTICIANS at a Ministry of Supply research establishment in the South of England for duties involving statistical advice on the design and results of experimental work in microbiological research, particularly in the fields of bacteriology and experimental pathology, biophysics and biochemistry—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4102/51 (December 13).

READER IN CLINICAL VETERINARY MEDICINE at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (December 15).

LECTURER IN GEOGRAPHY at the University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 31).

TUCKER-PRICE SCIENTIFIC RESEARCH FELLOWSHIP, for research in mathematics, science or an allied subject—The Secretary, Girton College, Cambridge (January 15).

ASSISTANT LECTURER IN THE DEPARTMENT OF MATHEMATICS—The Registrar, College of Technology and Commerce, The Newarke, Leicester.

BOTANIST (with honours degree) to undertake the investigation of marine ecological problems—The Secretary, Institute of Seaweed Research, Inveresk, Midlothian.

ELECTRICAL ENGINEERS (Experimental Officer grade) at the Royal Aircraft Establishment, Farnborough, for work on aircraft electrical generating equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.425/51A.

ELECTRICAL ENGINEERS AND PHYSICISTS at a Ministry of Supply research and development establishment near London—SENIOR SCIENTIFIC OFFICERS. ELECTRICAL ENGINEERS (Ref. D.390/51A) with special qualifications in radio communications and experience in the engineering of development prototypes, PHYSICIST (Ref. A.245/51A) with experience in electronic circuitry for research into the measurement of high-speed transients, and a PHYSICIST (Ref. 246/51A) with experience of optical and electronic techniques, and with an interest in fluid mechanics, for work on aerodynamics problems including wind tunnel investigations; SCIENTIFIC OFFICERS. ELECTRICAL ENGINEER or PHYSICIST (Ref. D. 392/51A) with interest in the application of electronic methods to optical instrumentation techniques, and an ELECTRICAL ENGINEER or PHYSICIST (Ref. D.391/51A) for work on high-speed electronic calculating machine—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

ELECTRICAL AND MECHANICAL ENGINEERS and PHYSICISTS (Experimental Officer grade), with experience in (*a*) generation and distribution of electrical power in aircraft, (*b*) general electronics, communication or radar, (*c*) aircraft structure and associated mechanical problems, or (*d*) servo mechanisms and automatic actuators, at the Royal Aircraft Establishment, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.483/51A.

ENGINEER (with specialized experience in electronic engineering, servo mechanisms, or fine mechanisms including hydraulic devices) at a Ministry of Supply establishment at Malvern, to take charge of a team of engineers investigating engineering and design problems, working with scientific staff on development of ground radar equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.482/51A.

ENGINEERING OFFICER (Wireless) IN THE POSTS AND TELEGRAPHS DEPARTMENT, Sudan—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Engineering Officer (Wireless), 4/58'.

EXPERIMENTAL and ASSISTANT EXPERIMENTAL OFFICERS at the Ministry of Supply Factory, Capenhurst, Chester, for research work connected with the construction and operation of an atomic energy factory—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs.

GRADUATE LECTURER IN ELECTRICAL ENGINEERING at Lincoln Technical College—The Chief Education Officer, City Education Office, 4 Lindum Road, Lincoln.

HEAD OF THE DEPARTMENT OF ENGINEERING AND MINING at Wakefield Technical College—The Director of Education, 27 King Street, Wakefield.

HEAD OF THE ELECTRICAL ENGINEERING DEPARTMENT—The Registrar, Loughborough College, Loughborough, Leics.

HORTICULTURAL SUPERINTENDENT—The Principal Agricultural Officer, Lancashire County Institute of Agriculture, Hutton, Preston.

LECTURER (with a university degree in engineering, or equivalent qualification, and practical experience in the electrical industry) IN THE ELECTRICAL ENGINEERING DEPARTMENT—The Principal, Northampton Polytechnic, St. John Street, London, E.C.1.

MECHANICAL AND ELECTRICAL ENGINEERS (New Construction) in the Public Works Department, Sudan—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Mechanical Electrical Engineer 4/220'.

PHYSICAL CHEMISTS IN THE DIVISION OF ATOMIC ENERGY (Production), Research and Development Branch, Culcheth, Warrington, to assist in research on corrosion, electrochemistry, thermochemistry, surface chemistry and constitution of alloys—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs.

PHYSICISTS at a Ministry of Supply research establishment in Berkshire for work of a research and development character concerned with the use of radioactive materials, radiation measurements and health physics—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.538/51A.

SCIENCE OF ENGINEERING GRADUATES to do research on some aspects of the flow of liquids through porous surfaces—The Registrar, Imperial College of Science and Technology, South Kensington, London, S.W.7.

PROVISION OF FURTHER EDUCATION

THERE are already clear indications that mounting costs alone will necessitate in the near future some careful scrutiny of educational expenditure in Great Britain and some re-determination or assessment of priorities, even if it is possible to maintain the votes from Parliamentary funds at their present level for current expenditure, quite apart from capital grants. One such pointer at the university-level is the plain warning given in the last annual report of the University of Oxford that deferment of building applications will be for longer periods in future, and the admission that the joint building committee of the University and the colleges has already been compelled to choose between the new Inorganic Chemistry Laboratory and the next stage of Nuffield College. The Workers' Educational Association has examined some of the issues in its recent pamphlet on educational expenditure, and the postponement of the county colleges scheme received adverse comment at the Association's conference at Harrogate in October. The statement regarding the mounting cost of school text-books, which the Educational Group of the Publishers Association has prepared, directs attention to a factor which affects education at all levels, although it presses chiefly on the estimates in the schools.

In this situation, with the severe limits which the rearmament programme is likely to set for some years to come to the proportion of the national resources of Britain which can wisely be allotted to education, it is imperative that there should be careful forethought and searching discussion over the whole field before action is taken. Although in education, as elsewhere, there may well be opportunities, and especially on the administrative side, for numerous small economies appropriate to a time of austerity or emergency, which in the aggregate might prove substantial, it is essential that such economies should not be taken without regard to possible repercussions elsewhere. Otherwise educational policy may well become unbalanced, and quality and standards may be sacrificed to quantity, with perhaps irreparable damage to long-term interests. At least a hint of this possibility is given in the Statement on Higher Technological Education issued in September.

If such consequences are to be avoided, educational bodies of all kinds should be looking ahead and deciding for themselves what pruning would be wise, what measures or developments could safely be postponed, and what expansion is imperative even at the present time. The argument for such expansion should be developed so that the case can be cogently urged and presented against the background of other claims for full consideration at the appropriate level for approval and action. This is clearly being done in some quarters, as the report from the University of Oxford already mentioned shows; but what is less certain is that proper regard is being had to the inter-relationships of education policy at the different levels and the opportunities that may exist for readjustment and possibly economy by some co-operative action.

The survey of the English universities and adult education which has recently been made by Mr. S. G. Raybould, director of the Department of Extra-mural Studies in the University of Leeds, and published by the Workers' Educational Association*, is timely for two reasons. First, it provides an excellent exposition of the fundamental importance of adult education for the effective functioning of our Parliamentary institutions and indeed of democracy in general, and shows the dependence of good adult education upon education policy and practice at all levels from the universities to the primary schools. It is a resultant of numerous factors, and this survey is a welcome reminder of the need for caution in dealing with a complex situation. Secondly, Mr. Raybould's survey emphasizes the need for a thorough re-consideration of the place of the universities in extra-mural work, and the nature and extent of their contribution to adult education. It is clear from his book that some universities at least are far from having given the thought and attention which this work demands: they are not even clear as to whether or not extra-mural work or adult education are appropriate functions of a university. If the universities are not clear as to the justification for an expenditure which Mr. Raybould estimates elsewhere as of the order of half a million pounds in 1949–50, mistakes—possibly disastrous mistakes—are likely to be made at a time of retrenchment.

The extra-mural work of the universities in Britain has been twice reviewed in this century in published reports: first, in the report of 1909, under the title "Oxford and Working class Education", which contributed largely to the development of the university tutorial class and the institution of university joint committees for tutorial classes in every university in the country, and ten years later in the final report of the Adult Education Committee of the Ministry of Education. Many of the recommendations of the latter Committee, including that for the establishment at each university of an extra-mural department with an academic head, have since been implemented. There is now only one English institution of university rank without such a department; but no reports of comparable standing, reviewing developments and assessing needs in relation to thoroughly considered and clearly stated principles, have appeared during the past thirty years; and it is clear that, apart from the present emergency, some such review is urgently needed to guide the expansion of university work in this field and to resolve the doubts and hesitancies of some universities by facilitating both general agreement as to the proper functions of the universities in this field and the common policy they might pursue.

References in the reports of the University Grants Committee indicate that the question has not been entirely overlooked. The report for the quinquennium 1929–30 to 1934–35, which accepted the view that adult education is an integral part of the normal activity of the universities, with a legitimate claim on their interest and financial support, recognized even then that new factors like broadcasting were changing the educational background. In the subsequent report issued in 1948, and again in Sir Walter Moberly's book "The Crisis in the University" a year later, the arguments against university participation in adult education were set forth succinctly. The position of the universities in relation to their regions, against which their extra-mural work now increasingly tends to be focused, have been set forth in general terms in Bruce Truscot's "Redbrick and these Vital Days", in Prof. B. Dobrée's Earl Grey Memorial Lecture in 1943 and in articles in *The Universities Quarterly*. There has not, however, been the detailed examination of present arrangements and performance which could contribute much to establishing the soundness or unsoundness of the criticism of university participation in this field.

Mr. Raybould recognizes that any such examination cannot be entirely conclusive, because only in part is the examination of statements of fact possible: even such facts as can be assessed do not necessarily indicate adequately what might be possible, and some of the most important elements for a qualitative judgment cannot be readily communicated in words, except possibly to those with first-hand acquaintance with adult education in practice. The quantitative aspect, too, is important at this juncture, and Mr. Raybould has attempted in his book to bring together information on the relations between extra-mural and internal work, the nature and duration of courses and the kinds of tutors employed, and to put it alongside the criticisms advanced in the University Grants Committee's report and Sir Walter Moberly's book.

Attention is rightly directed by Mr. Raybould to the help which the universities might give appropriately by promoting systematic thought and inquiry about adult education as a distinctive branch of study; but this alone is not enough. There was never a time when there was greater need at the Ministry of Education for more imagination, creative thinking, vision and energy, if an adequate education policy is to be implemented. This is essential to ensure not merely that the growing generation is adequately trained to play its part in the complex world of to-day, but also that the proper balance is maintained between the different levels of education, the best use made of our limited resources of materials, and proper provision made for further education, on which both industrial efficiency and productivity and equally the smooth functioning of democratic institutions depend. This is not a matter which concerns the Ministry alone; the universities and the University Grants Committee and industry have their own parts to play. But the critical part is that of the Ministry of Education; and however fully the universities respond to Mr. Raybould's challenge, the future of adult education, and the extent of its contribution to technical efficiency and productivity and the functioning of our democratic institutions, will depend largely on whether Miss Florence Horsbrugh, the new Minister of Education, brings to her office more than administrative ability; she must have also the vision and grasp of essential issues, the firmness of decision, and the energy in action which are required alike to resist sectional pressure and to promote the policy which the country needs. Educational policy is of such critical importance, and the damage which unwise retrenchment can do is so great and irreparable, that the exclusion of the Minister of Education from the new Cabinet will be viewed with regret by all who appreciate what is at stake. It cannot but make Miss Horsbrugh's task more difficult in securing either the right economies or the increased spending which in technical education, and especially in technological education, is imperative even to-day.

LECTURES ON THEORETICAL PHYSICS

Vorlesungen über theoretische Physik

Von Prof. Arnold Sommerfeld. Band 1: Mechanik. Vierte, neubearbeitete Auflage. Pp. xii+276. 18 D. marks. Band 2: Mechanik der deformierbaren Medien. Pp. xv+376+4 plates. 18 D. marks. Band 3: Elektrodynamik. Pp. xvi+368. 18 D. marks. Band 6: Partielle Differentialgleichungen der Physik. Pp. xiii+332. 18 D. marks. (Wiesbaden: Dieterich'sche Verlagsbuchhandlung, 1947–1949.)

A CYCLE of lectures on theoretical physics is a normal feature in a Continental university. The lectures, which would be attended in general by mathematicians and physicists, form a three-year cycle; each section is made self-consistent. The present series is based on such a cycle, given by one of the greatest teachers of theoretical physics. In Great Britain, where theoretical physics is just beginning to be recognized as a separate subject, some of this material would appear in lectures on applied mathematics, some as part of a physics course and some of it not in any undergraduate course. These books, therefore, cannot serve directly as texts for any of the standard courses, but they provide many ideas that could be incorporated with advantage. The emphasis is always on the physical concepts. Mathematical techniques are developed, where they are necessary, with Sommerfeld's characteristic skill, but they are never allowed to become aims in themselves.

The course on mechanics covers, in one semester, what would take about two years in a British honours course. Of necessity, therefore, it is somewhat short on points of detail, but what is omitted is mostly manipulation. Statics, as such, occupies only about five pages, and this in my opinion represents a correct assessment of its didactic value. There is a good selection of examples which provide a welcome change from the 'ladder-leaning-against-a-wall' type. This is followed by a section containing detailed and instructive comments on the solutions of each problem.

In the second volume hydrodynamics and elasticity are treated together. Thus the general principles can be treated in a concise and transparent way. The emphasis is very strongly on the general principles, in this case somewhat at the expense of mathematical techniques. In the later sections on hydrodynamics, such relatively advanced problems as boundary layers and turbulence, as well as supersonic flow and shock waves, are mentioned, whereas the treatment of the theory of potential flow is brief and the method of complex variables has been completely omitted.

Vol. 3 builds up Maxwell's equations from the familiar integral theorems, giving enough examples to bring out the significance of each term in the equations, and the later chapters then show how one solves them. Here again, potential theory is passed over quickly, whereas those problems the solutions of which involve new physical principles are discussed at length. Relativity and the Lorentz theory of the electron are covered fully, and there is a short chapter on the equations for moving media.

In the preface to Vol. 6, on the differential equations of mathematical physics, Sommerfeld refers to "the pre stabilized harmony" between what is interesting mathematically and what is relevant physically; and, in fact, this volume illustrates particularly well his attitude to mathematics, in his insistence on correlating his mathematics with the physical situation at every step. In every case the object of a mathematical argument is not to provide rigorous proof, though he is quite capable of rigour where the validity of a step is in doubt, or where one has to guard against dangerous exceptional cases. But the chief interest is always in showing a new concept to be reasonable, because it corresponds closely to a significant feature of the physical situation, and to be useful for getting practical results. Fourier series and integrals are discussed together. The general properties of partial differential equations, including their characteristics, are summarized and illustrated by a full discussion of problems in heat conduction. A chapter on spherical harmonics and Bessel functions is followed by a discussion of eigenvalue problems in general, and the last chapter, by way of illustration, covers the classical theory of radio waves, to which Sommerfeld has made so many basic contributions.

To me these volumes represent an almost perfect choice of topics for a basic course on theoretical physics, though I must admit some prejudice in this matter, having learnt most of my theoretical physics from Sommerfeld's lectures. It is not clear whether the missing two volumes on optics and on thermodynamics and statistics are to be published; it would be a serious loss if before his death Sommerfeld had not carried the work on these to a point where others could complete it. I shall eagerly await an English translation of this series, so it can be made available to at least some English-speaking undergraduates.

R. E. PEIERLS

ELEMENTARY GENETICS

Elementary Genetics

The Physiology of Descent. By Wilma George. Pp. vii+172. (London: Macmillan and Co., Ltd., 1951.) 10s. 6d. net.

WRITING an elementary book on genetics is certainly a difficult task: a large number of essential facts, the theories that unify them and some speculations as to future developments have to be concentrated into less than two hundred pages. None of the previous few books of this kind succeeded in striking a sound balance and the present one is no exception. In one important respect, however, it distinguishes itself, namely, the large amount of relevant and well-chosen factual information which it conveys very successfully. For this reason alone this book constitutes a valuable contribution. The non-specialist student who wishes to gain a general idea of the experimental evidence on which genetics is based will find the answer here. The choice of appropriate examples is definitely an original and useful feature of this book. Also commendable is the stress laid upon the part played by genes in morphogenesis and in particular the way in which this matter is treated in a chapter on gene-interaction.

Other good features are the treatment of mutation, including a summary of the biophysical approach, and that of the genetic aspects of evolution, compressed into two clear chapters. Statistical methods appear not once in the whole book, a matter which may be regretted even by those, like the reviewer, who consider statistics as a useful, indeed indispensable, evil. Among the serious shortcomings of the book is a lack of critical attitude which leads to confusion about the fundamental concepts of genetics. For example, clear definitions of gene, allele and locus are not given, and these terms are used inconsistently.

Despite these shortcomings this book is an attempt to produce something which is badly needed, and it is certainly the most successful of these attempts.

G. Pontecorvo

FREUD'S "TOTEM AND TABOO"

Totem and Taboo

Some Points of Agreement between the Mental Lives of Savages and Neurotics. By Sigmund Freud. Authorized translation by James Strachey. Pp. xi+172. (London: Routledge and Kegan Paul, Ltd., 1950.) 14*s*. net.

IT is interesting to re-estimate the value of a work originally published nearly forty years ago. This book of Freud's first consisted of four essays published in *Imago* and represented his earliest attempt to apply psycho-analysis to problems of social psychology. The book aimed at arousing the interest of a wide circle of educated readers, and succeeded. The reaction, on the whole, except among those already attuned to psycho-analytic concepts, was one of acute shock. This was so among anthropologists as much as any, since the main themes taken for analysis—incest, exogamy, taboo, magic and totemism—were important to anthropological theory, and Freud used much anthropological material in his analysis, while going far beyond the bounds of the then range of anthropological thought.

On re-reading the book after a lapse of time one finds the shock much reduced. There are the same ethnographic lacunæ and mistaken generalizations, the same feeling of unreality about the mental lives of the 'savages' in whom Freud saw so many points of agreement with neurotics. Any treatment is bound to seem defective if it includes such statements as that originally totems were inherited only through the female line (p. 107); that totemism constitutes a regular phase in all cultures (p. 108); that the desire to break taboos is always unconscious (p. 31); that in primitive men the process of thinking is still to a great extent sexualized (p. 89); that primitive men are uninhibited, thought passing directly into action (p. 161). Further, the hypothesis of the break-up of the primal patriarchal horde by the killing of the father and eating his remains is just as ludicrous as ever, when put forward as a *historical* occurrence and the basis of the commemorative act of the totemic meal.

But there is more strength and subtlety of argument in the book than anthropologists were originally prepared to credit it with. Even the fantasy of the murder of the patriarchal father may have a certain suggestiveness if looked at not as history but as hinting at a possible set of symbolic elements in totemic rites. Freud's own critique of the totemic theories of the time is usually shrewd and, in its stress on the need for examining emotional rather than rational characteristics of the phenomena, on sound lines. His support for the arguments against explaining horror of incest in terms of innate instinct was powerful, and well directed. His frank admission of ignorance as to origins of various savage customs is refreshing. Where in part he is vulnerable is where he forgets his own dicta—as in suggesting that the Australian 'marriage-classes' originated in deliberate legislation to prevent incest when the influence of the totem rules began to wane.

Modern social anthropology would not agree with Freud that it is precisely the incestuous factor in the mother-in-law and son-in-law relation that provides the motive for the avoidance that so frequently is customary between them. Compatibility of social rather than sexual elements in the total social situation is the line of explanation now advanced. Yet in Freud's citation of impulses involved in the situation of ambivalence—reluctance of the mother-in-law to give up her daughter, distrust of the stranger to whom the girl is to be handed over, impulse to retain the dominant position in her daughter's house, man's determination not to submit his wife to another authority than his own, etc.—there is much valuable suggestion for further study. Relations between social anthropology and psychology are still ill-defined and unstable. But in any resolution of them the work of the psychoanalysts must be taken very seriously into account. It is very useful, then, to have this new translation of the pioneer work.

Raymond Firth

THE SMITHSONIAN INSTITUTION

The Smithsonian

America's Treasure House. By Webster Prentiss True. Pp. 306+64 plates. (New York: Sheridan House; London: George Allen and Unwin, Ltd., 1950.) 27*s*. 6*d*. net.

"THE best blood of England flows in my veins; on my father's side I am a Northumberland, on my mother's I am related to Kings, but that avails me not. My name shall live in the memory of man when the titles of the Northumberlands and the Percys are extinct and forgotten."

So wrote James Smithson, a lonely Englishman and a bachelor, in the late eighteenth century. But Smithson was a chemist of note and a wealthy man in his own right, and it is perhaps one of the most unexplained acts in the cultural history of Great Britain that induced this Englishman to make provision in his will for the establishment in Washington, D.C., of the Smithsonian Institution for the increase and diffusion of knowledge among men. How conscientiously the American nation has carried out the spirit and letter of this will is now known to the world, though it is strange that it should have been left until 1951 for Mr. Prentiss True to tell this fascinating story. But even after Smithson's bequest, it was the remote chance of the death of his nephew some six years later, leaving no child, that gave Washington the glorious opportunity of establishing such a chain of cultural centres.

The United States National Museum with its thirty million objects is perhaps the best known museum in the world. On the other hand, it is seldom realized that nine other organizations, including the National Air Museum, National Gallery of Art, National Collection of Fine Arts, Freer Gallery of Art and the National Zoological Park are centred around the Smithsonian Institution. Has one man ever created such a focus of learning and knowledge and by a stroke of the pen benefited so many millions of his fellow men, chiefly in a country which he had never visited or apparently in which he was not particularly interested ?

The largest part of this vast organization is the United States National Museum, with its six Departments—Geology, Zoology, Botany, Anthropology, Engineering and Industries, and History. Mr. True deals in separate chapters with the work of these Departments, and in a popular and entertaining manner shows how the Museum has made each subject appeal to the general public and yet at the same time provide material for investigation by specialists. In other words, the Museum is both an exhibition and research centre.

In lesser detail, the author outlines the work of the Bureau of American Ethnology, where the history of the American Indians is recorded ; fascinates his readers by a description of the wild animals in the Washington Zoo ; discusses the rich collections of the National Gallery; and finally relates the many services of the Smithsonian which make available scientific and cultural knowledge in the United States to scholars all over the world.

The book will be read with a touch of envy by those in Great Britain, though coupled with gratitude that the chosen country has fulfilled to the uttermost the vision of James Smithson, the lonely English bachelor. To describe it as an attractive and well-illustrated account for the lay reader and full of suggestive ideas for the museum specialist sums up this entertaining book. F. S. WALLIS

JAPANESE MONOGRAPH OF LICHEN CHEMISTRY

Chemistry of Lichen Substances

By Prof. Yasuhiko Asahina and Assoc. Prof. Shoji Shibata (University of Tokyo). Pp. viii+300. (Tokyo: Published in Japanese by the Kawade Shobo Co., 1949.) 480 yen.

WILHELM ZOPF in a classic treatise[1] was the first worker to summarize all the work on the lichen metabolic products then known—some 148 compounds had already been isolated, characterized and named by Zopf, Hesse and other workers—and he attempted to systematize them by a chemical classification. Prof. Y. Asahina reviewed the field in 1939 in an article entitled "Flechtenstoffe"[2] in the light of some one hundred publications from his research school at the University of Tokyo. Later, Prof. T. J. Nolan, of the National University of Ireland, Dublin, surveyed all the lichen compounds the chemical constitutions of which had been established, using Asahina's classification with some slight modifications[3].

Recent work on the isolation and chemistry of these interesting compounds has been carried out by Prof. Alexander Robertson, first at the London School of Hygiene and Tropical Medicine and then at the University of Liverpool, and by Prof. T. R. Seshadri, of the Andhra University, India. Interest in lichen products has been stimulated lately by numerous investigations of their anti-bacterial properties with special emphasis on their activity as inhibitors of the tubercle bacillus. (See a review by Prof. F. Bustinza, University of Madrid[4].)

This new book by Profs. Asahina and S. Shibata, the first to summarize completely the field of the chemistry of the lichen metabolic products, is a valuable addition to our knowledge of the naturally occurring compounds. Although written in Japanese, it should be of considerable use to English-speaking scientific workers by virtue of its very many structural formulæ and complete literature references. I understand that a translation into English is being contemplated.

This publication, of some three hundred pages, has been written in three sections. Part 1 gives a brief historical sketch of lichen investigations ; a classification of lichen substances into their chemical groups ; while a third chapter deals with the methods of extraction, isolation and purification of the various metabolic products.

Part 2 describes in their groups the lichen source, history, properties, and the structural and degradative chemistry of some seventy-six pure compounds which have had their chemistry more or less completely elucidated. The following compounds, not covered in Prof. Nolan's review, are now described : rangiformic acid ; the depsides erythrin, hiascic acid and hypothamnolic acid ; pannarin (a depsidone) ; the anthraquinone pigment fallacin ; lichexanthone ; two dibenzofuran compounds didymic acid and strepsilin ; and the nitrogen-containing bitter substance picrorocellin. Diploicin, an unusual chlorine-containing depsidone, isolated along with several other chlorinated compounds from the lichen *Buellia canescens* (*Diploicia canescens* Dicks), is but scarcely mentioned on p. 122 and should have received more fuller treatment in view of the work of Nolan and his collaborators. Diffractaic acid and α-collatolic acid, names assigned to two lichen acids by Prof. Asahina, should be discarded since they are known (and stated) to be identical with the compounds already fully described by Zopf (*loc. cit.*) as dirhizoninic acid and lecanorolic acid, respectively.

Part 3 consists of chapters discussing the relationships between lichen substances and fungal metabolic products, with particular reference to the hydroxymethylanthraquinones ; some biogenetic interpretations of the formation of lichen compounds ; and finally some work which has been recorded on the antibacterial properties of numerous lichen products and their derivatives. Author, species and subject indexes are given in English as well as Japanese.

A BIOLOGICAL APPROACH TO PLANT VIRUSES

By Dr. J. S. KENNEDY

Agricultural Research Council Unit of Insect Physiology, Zoological Laboratory, Cambridge

VIRUS workers were recommended by Pirie[1] not to try to maintain a precarious position on either of two stools—the chemical, treating viruses as molecules, or the biological, treating them as organisms—but rather to "settle comfortably on the floor", that is, adopt a biochemical approach. The purpose of this article is to suggest a broader biological approach to plant viruses. The bare answer to the question 'What are viruses ?' will undoubtedly be biochemical, and fundamentally important, but still bare and incomplete. A biological approach to viruses would be through their relations with the whole system—biochemical, physiological and ecological—of which they form a part.

Plant virus research has not, in fact, developed in such an all-round biological way. It was agricultural practice which directed attention to the problem in the first place, and workers on the more practical side have had to pay continued attention to the wider relations of viruses. But the theoretical background for their work is provided by a research trend which has been narrowing on to the virus itself. "The isolation of tobacco mosaic virus by Stanley in 1935," as K. M. Smith[2] has said, "was the key that opened the door to the study of the virus itself, quite apart from the disease it may cause." Thereafter, as Bawden and Pirie[3] have said, "most work so far has been directed toward obtaining apparently homogeneous preparations with the highest infectivity", as if viruses could best be understood in isolation. Study of the means and conditions of virus spread continues apart, as if it could make no comparable contribution to virus theory. Nevertheless, biochemical work has led to the conclusion that "the ability to spread, or to be actively infective, is the one character that clearly distinguishes viruses from other cell constituents" (Bawden[4]); and although insects provide the commonest known means of spread, it is symptomatic of the way virus theory has developed that these vectors are regarded as *nothing but* vectors. They are presented as unequally efficient, but essentially *indifferent*, 'accidental' collectors and deliverers of virus. "There is very little evidence," writes K. M. Smith[5], "to suggest that an arthropod vector of viruses is in any way affected by the virus it may transmit. Even where there is good evidence that the virus multiplies inside the body . . . the insects do not seem to be adversely affected." Or Bawden[4]: "Most workers have failed to find any significant differences between infective and non-infective individuals of vector species. . . . Infective individuals live as long and breed as freely as non-infective". The assumption implicit here is that what is pathogenic to one organism, the plant, is of no biological significance to the other, the insect, if it is not pathogenic of that too; so that the virus is nothing but a pathogen, intrinsically.

There is, of course, a third possibility. The vector might be importantly affected—might even gain—from its carrying of plant pathogens, not necessarily through a direct physiological action of the virus in its body, but ecologically, through an indirect effect of the virus *via* the host plant. But there is no room for such an idea so long as ecological aspects of the problem are considered under the one-sided headings of 'spread' or 'transmission' and omitted from the consideration of insect–virus relations[4,6]. Although Leach's[7] eleven-year-old plea for more work on the biology of insect–virus relations has not been rejected as unsound, it has been passed over.

The general grounds for such a plea seem more than adequate. Most plant viruses depend on insects for their spread, and as Bawden[4] says, "New vectors of plant viruses are constantly being discovered and there is no doubt that many viruses for which the only methods of transmission now known are grafting or sap inoculation are also transmitted by certain insects". Secondly, there is a considerable measure of specificity in virus–vector relations, even if it is not as great as was thought. Thirdly, the vector's role in transmission is not merely mechanical, carrying the virus as an accidental contaminant on its body, but a more subtle and little-understood one. That is so, not only with 'persistent' viruses having a 'latent period' in the insect, but even with the 'non-persistent' ones which can be transmitted very quickly indeed. Fourthly, Black's[8] work has now left little doubt that at least one plant virus can be multiplied and maintained through many generations in its insect vector feeding on apparently healthy plants, thus blurring somewhat the distinction between the 'independent' viruses and the phytotoxic secretions elaborated by many insects. Some of these secretions cause systemic pathological changes in the plants[8], and the toxicity of the insects may vary with the kind and stage of growth of the plant previously fed upon and may even be intensified by breeding successive generations of insects on a susceptible plant[9]. As Leach[7] said: "Numerous cases have been cited of the evolution of an association of insects and microorganisms for mutual benefit. There is no convincing reason why association of insects and viruses may not have arisen in a similar manner. . . . The question of whether a virus-infected plant is a more favourable host than a healthy plant for the insect vector has been given very little attention in virus studies. . . . The problem offers a fascinating field of research, and its solution should be of fundamental significance in the fields of both plant and animal pathology."

Leach was then able to cite only one case, unlooked-for but documented, of benefit to the vector, and to suggest another as probable. Carter[10], studying the populations of *Thrips tabaci*, the vector of the virus of yellow spot disease of pineapples in Hawaii, on alternative hosts, in particular the weed *Emilia sonchifolia*, which is also susceptible to the disease, noticed that "populations on diseased *Emilia* are consistently higher than those on healthy *Emilia*. . . . The explanation for this is probably that while healthy *Emilia* normally grows rapidly, matures and dies, diseased plants may persist for a longer time with a mass of curled leaves affording satisfactory shelter for *Thrips tabaci*. It seems to be demonstrated that when *Emilia* functions as a reservoir of the yellow spot virus it is also a more suitable host for *Thrips tabaci*." Carter[11] also found that high humidity was unfavourable to *Eutettix tenellus*, the vector of sugar beet curly-top virus. Diseased plants are stunted, forming more open stands than the dense luxuriant growth of healthy plants. Hence, Leach suggested, "if the leaf hoppers were not vectors of the curly-top virus, the sugar beets would grow normally and in all probability would not be a favoured host of the leaf hopper".

Since then, another case concerning leaf hoppers has been worked out in some detail by Severin[12], who was deliberately seeking an effect of the disease, aster yellows, through the plant, celery, on a number of vector species. He found that the insects developed faster, lived longer and reproduced more on the diseased than on the healthy plants. In most cases the difference was quite clear-cut, the insects dying off in a few days when put on healthy plants, but building up flourishing colonies when put on diseased ones. "There are numerous leaf hopper species," Severin says, "which live on diseased celery and asters, but when transferred to healthy plants they die." These plants, then, are not ordinarily suitable hosts for these insects, but by means of the virus, the insects can make them suitable—if not for the individuals first infecting a plant, then for later arrivals. Even if that action were originally accidental on the insects' part, it is difficult to believe that it would remain so for long.

Two further cases recently brought to light concern the most notorious plant virus vector, the aphid *Myzus persicæ* (Sulzer), and the important potato diseases, leaf-roll and severe mosaic, which are among those caused by viruses this insect transmits. Arenz[13] has shown experimentally that the vector multiplies substantially faster on potatoes with either of these diseases than on healthy ones.

The latest case concerns the black bean aphid, *Aphis fabæ*, and here the benefit of the plant disease to the vector appeared not as an isolated observation but as a particular application of a general principle running throughout these insects' host-relations. The principle is that the aphids feed and reproduce poorly, if at all, even on their favourite host plants, if the insects are confined to fully functional, robust green leaves which have ceased growth and not yet entered upon senescence. They thrive, on the other hand, on the same leaves while they are actively growing or senescing[14–16]. The aphids have not only 'botanical' preferences which confine them to specific kinds of plant, but also 'plant physiological' preferences which confine them to the more nutritious stages or parts of those plants. It follows that altering the physiological condition in which a plant customarily is when the insect finds it in Nature, would change that plant's status as a host for the insect. For example, *Aphis fabæ* will readily colonize crocus if the plant is in active growth, before flowering, when offered to the aphid. In Nature, crocuses are well past that stage when the aphids are first on the wing. They are not, therefore, colonized by, and do not rank as hosts of, *Aphis fabæ*. But any change which brought crocuses out later relative to the aphids would enable the aphids to colonize them habitually. That in turn would facilitate the aphids' development of a 'botanical' preference for crocuses in due course.

The pathological conditions known as plant galls and virus disease also involve physiological changes which, by the same token, might be expected to benefit the insects that initiate them. Galling and virus disease typically involve either abnormally extended growth or premature senescence-like changes, or both. They tend thereby to suppress that stage in the leaf's life which is most unfavourable to the aphids. How far the relationship between insect and plant in galling is symbiotic has been a matter of lively, if inconclusive, discussion. That the insect does, in fact, live on "nutritive tissues produced especially at its order by the plant"[17] in the more elaborate, 'determinate'[18] or 'prosoplasmic'[19] galls is generally conceded. There has been more uncertainty about the more primitive, 'indeterminate' or 'cataplasmic' galls which are produced by many aphids and take the form of simple distortion, rolling or pocketing of leaves. Went[20] suggested that the "very simple malformation . . . bulging of the intercostal areas of the leaves, giving rise to the formation of pockets in which the aphids are well sheltered . . . can be explained satisfactorily by assuming auxin destruction in the phloem". Apparently he regarded this effect much as he regarded crown-gall: as purely pathological, an accident so far as the causative organism was concerned. This probably represents the general opinion concerning such 'pseudo-galls' caused by aphids.

Experiments on the pocket galls formed by *Cryptomyzus ribis* on red currant leaves[21] indicated that they were, in fact, beneficial to the insects responsible. If the benefit had been a merely mechanical, protective one, as Went suggested, it would be easier to regard it as accidental. But the galls were physiologically beneficial, since the aphids fed preferentially and reproduced faster on the lining surface of the galls even when they were everted so that the insects there were completely exposed. Experiments on sugar beet mosaic disease[21] showed that this also was beneficial to a vector, *Aphis fabæ*, of the virus concerned. On the average, the aphids reproduced nearly one and a half times faster on diseased plants than on healthy ones. Not only the mature leaves but also the growing and senescent ones were more suitable for the aphids when showing disease symptoms than when healthy. As a result, the aphids on diseased plants became overcrowded and emigrated sooner than from healthy plants, so that the virus presumably facilitates its own spread in the field by this means.

The established cases of virus diseases benefiting the vectors are still very few, and further work should clearly be concerned not merely with the effects of the diseases on their vectors but also on non-vectors. There is no *a priori* reason for supposing that only vector species benefit from a disease in the plant, any more than there is for supposing that such benefit accrues to all vectors. But it does begin to appear that the economic importance of plant virus disease may owe a good deal to the 'boosted' multiplication of infective insects; and the fact that the established cases were selected for study simply because they were economically important, and not because they seemed especially likely to show the beneficial effect, does make it no longer seem permissible to consider the role and even the origin of plant viruses without due attention to the vectors. It is true that the instability introduced into insect–plant relations by the progress of agriculture seems likely to work against the development or persistence of symbiotic associations as envisaged by Leach. But his analogy with symbiosis between higher organisms must not be pressed too far; it is doubtful whether viruses have the necessary degree of independence and permanence to rank as one of the partners in an ordinary symbiosis. Sub-cellular by nature, they may achieve that rank only conditionally and temporarily.

In those cases where galling and virus infection both are, in fact, methods by which insects 'pre-digest' plants, they would seem to complement one another, inasmuch as the one method will serve when the other will not. There is marked specificity in the relations between the aphids and the plants which respond to them by producing galls. Hille Ris Lambers[22] holds that the longer, phylogenetically speaking, an aphid has been associated with a given plant, the greater the tendency for a galling response to have developed. There is less specificity between insects and plants so far as virus disease is concerned. One virus may have many vectors and many hosts, some of which are symptomless 'carriers', and one insect may transmit many viruses. It would seem to follow that a virus causing a disease which benefits the insect vector would serve it particularly well in attacking new host plants to which it was not previously adapted. Such plants will not respond to the local, specific stimulus of the insect by the local and circumscribed type of 'pre-digestion' known as galling, because there has not been the necessary long period of mutual adaptation beforehand. Where coaxing fails, a bludgeon may succeed. Virus inoculation is a bludgeon in that sense, causing the drastic diversion of the plant's whole metabolism which is called a systemic disease. If in this way virus transmission enables the insect to cross the bridge from host plants to which it has become adapted, to new plants, the insect can then become adapted to them, too, in due course, with the eventual formation of new species, as already suggested in connexion with non-pathological physiological changes in plants.

Galling and virus disease are both abnormal diversions of the plant's metabolism, but once started the disease is more independent of the insect than the galling response. So far as we know, most virus vectors are not infective before they have pierced an already infected plant. Many plant viruses to-day do not depend on insects for their spread. These facts speak for the relative independence of viruses, and support the prevailing view that the origination of a virus may owe nothing to an insect. Yet, since both galling and virus infection can be, in effect, insect weapons, it is at least possible that the second sometimes arose from the first. The conditions for this leap, by some extension leading to partial emancipation of the insect-induced metabolic deformation of the plant, might be reproduced experimentally. Picturesquely speaking, the insect might be likened to a sorcerer evoking strange but nicely controlled plant growths, while the virus would be the sorcerer's apprentice, dependent, but notoriously undisciplined.

Bawden[4] has directed attention to the need for studies on the physiology of virus-infected plants, and it would seem worth while to make parallel studies on leaf ageing and galling as well. Growing, senescing, galled and virus-diseased leaves evidently have something in common from the aphid's point of view. If we knew what that was, we should know more not only about aphid nutrition but also about the virus disease. Viruses, according to Caspersson[23], "appear as parasites on the system for protein formation of the host cell, indicating that their own system for that is incomplete", whereas aphids are, presumably, more self-sufficient for protein formation, given an adequate supply of amino-acids. So far as mere multiplication goes, aphids and viruses may have rather similar requirements. But the virus, as Bawden and Roberts[24] have suggested with some experimental support, has an additional prior requirement before 'multiplication' can begin: re-direction of the plant's protein synthesizing processes. Parallel observations on aphid and virus might therefore help to distinguish the postulated two stages in the process of virus infection.

These are particular questions. To direct attention to them is not to assume a pre-eminent role for the insect in virus biology. The main point about even one or two cases of vectors which benefit from the disease caused by the virus they carry is that they are unexpected as a matter of principle. They have been discovered in spite, rather than because, of the existing theory. Plant, insect, virus and disease together form a biological complex involving biochemical, physiological and ecological relations. The whole and the parts have a history, and being biological that must involve adaptations. It is then through the study of their relationships, and in the expectation of adaptations, that the role of each component can be understood, and in no other way. A shift toward that general point of view, away from the cramping conception of viruses as "complete and self-sufficient systems" (as Bawden[4], an opponent of this conception, has expressed it), has been a notable result of recent biochemical work on plant viruses. Evidence is accumulating against both the older pictures of self-sufficient viruses: either as self-reproducing or as forcing the plant to produce their like[25]. The infection imposes a whole new metabolic pattern on the plant, and virus "individuality becomes merged into that of the infected cell"[4].

Superficially similar conclusions have been reached lately with regard to various animal viruses and bacteriophages. It has been found that the free phage particle "loses its identity after entering its host. . . . It merges with the bacterial organisation and with other phage particles" to form a "new entity, the phage-bacterial complex" wherein the phages are presumed to be temporarily disintegrated into gene-like fragments[26]. An analogy is the 'masking' of animal viruses in their intermediate hosts[27], or the evidence that certain bacteria may pass through a submicroscopic phase in the host[28]. But here the evidence is not mainly biochemical, and according to Luria[29] the 'ultimate goal' in phage studies is still seen as "the identification of the elementary 'replicating units' of biological material and the clarification of their mode of reproduction", on the assumption that "reproduction must involve point-to-point replication of some elementary structures responsible for the conservation of specificity from generation to generation", these units being by definition exogenous. Thus the main development in phage theory is the transfer of interest from one kind of particle to another, smaller one, and the guiding conceptions are those of formal genetics.

Plant virus research, on the other hand, has become less preoccupied with specific particles large or small. Evidence that the virus merges into the metabolism of the infected plant has not intensified the search for supposedly ultimate, inviolate particles, but has brought a change of emphasis, on to the activities of "the whole [host] cell, in which the virus is only one determining component"[4]. "To attribute any independent existence or activities to viruses may be a misconception", says Bawden[4], ". . . The purified virus may be only a part of a larger active system, and in studying the part it is important not to overlook the whole"; and Pirie[1] asks, "Is there any *a priori* reason for assuming that infection can lead to the production of only one anomalous nucleoprotein or that the ability to initiate infection in a new host is a property restricted to one ideal unique structure ? Clearly there is not." That this trend in virus theory should originate with workers directly investigating the biochemical, intracellular events is characteristic of a biological theory postulating self-sufficient entities. The closer one gets, without actually going outside the living context altogether, to the postulated ultimate particles themselves, the less self-sufficient they turn out to be. It took an even more painstaking and intimate study of living relationships to dispose of the theory of special creation, which was a theory of the same general type applied to whole organisms.

The new trend in plant virus theory is not, however, consistent. A simply biochemical approach to the problem is not yet a fully biological one, so long as the pathogens remain 'self-sufficient' in their other, physiological and ecological, relations. The arguments Pirie[1] advances for examining all the biochemical peculiarities of infected plant tissue, not restricting attention to what it is hoped will prove to be the virus itself, apply with equal force to the higher-order relations of viruses. If as Bawden says the physiology of infected plants has not received enough attention, that is partly because, if the infective agent is self-sufficient, the main thing is to isolate it ; host physiology is incidental. Even the non-'self-sufficient', biochemical approach incurs some responsibility here, inasmuch as it has led to the view that the other-than-biochemical relations of viruses may be merely incidental. It is one thing to stress the merging of virus into cell metabolism, or that viruses may have existed as non-pathogenic constituents of one plant species until implanted into another. But it is another thing to say that viruses may originate in "occasional accidents", or that, in the definition of a virus, "disease-production . . . is included largely as a matter of convenience" (Bawden[4]). From a biological point of view, to treat the fact that the known viruses cause disease as a mere matter of convenience or definition, in other words, as an accident, seems at best premature. Even if this property were acquired 'by accident' originally, the physiological and ecological consequences, in an evolving biological system, can scarcely fail to have moulded the further history of the agents in a distinctive way.

Ecology, the very arena of evolutionary change, still seems to be regarded as the least interesting, the least fundamental aspect of virus biology, although it remains a pressing concern of more practical workers. This is seen in the one-sided view of the virus–vector relationship already mentioned. Bawden's[4] suggestion that "the causing of disease may be incidental to other activities and with little permanent significance to the evolution of the agent", again seems to treat viruses as a law unto themselves. Disease-production need not be a permanent property for it to have permanent evolutionary significance. If disease-spreading can benefit the insect and thereby involve it in the evolutionary consequences already outlined, then we cannot exclude important evolutionary repercussions on the virus. An agent which, through the disease it causes, actually multiplies its own vectors, has an obvious evolutionary advantage over one that does not.

This advantage will of course be offset, in varying degree, by the evolutionary disadvantage of the disease to susceptible plants, which would set a limit to the disease-producing activity of the virus in Nature. When circumstances—such as the growing of a new crop in the district—put a premium on the insects' ability to transfer from their established host plant to a new kind of plant not at first acceptable in its healthy state, then the advantage of a disease which rendered the new plants acceptable would be especially great. Once the insect had established its 'bridgehead' among the new plants in this way, and began to become more specifically adapted to them, then the advantage to insect and virus of beneficial disease in the plants would diminish, relative to the evolutionary disadvantage of the disease to susceptible plants and through them to the insect and virus also. This hypothetical sequence is presented merely to show there is no reason for expecting virus disease to be always and everywhere beneficial to insect or virus, but that there is a neglected approach here worth exploring. Ecological circumstances can be postulated which would sometimes call out and sometimes suppress the disease-producing function. There could be a varying 'demand' on the part of the insects for disease-production by virus in plants. Starting from this end might lead to earlier and fuller understanding of the origin of some virus diseases and viruses, than starting from the 'ultimate' causes, the isolated pathogenic particles.

However, the insect's contribution here is only a special aspect of a generally recognized fact, that it is man's ecological intervention, by growing plants as crops, which creates disease problems in any event, with or without the aid of insects. This, again, is often thought of as a merely incidental effect, given a virus 'there in the first place', self-sufficiently independent of ecological conditions. Since ecological relations are the very means of evolution, they cannot be treated as incidental. If they serve to multiply and perpetuate 'given' viruses, it is in them we must look for the origin and development not only of epidemics but also of viruses.

The mysteriously self-sufficient virus particle, although expelled from the biochemical context, still lives on in the ecological context. So long as this remains an implication only, it will not be easy to carry the current movement away from the self-sufficient conception of viruses, beyond the biochemical into the other contexts. The logic of this example of what is called a particulate theory in biology needs explicit statement. A particulate theory, in this sense, is one which endows material substances, particles or processes with an unnatural degree of independence. Thus the virus itself has been dubbed 'life's enemy'—something which is scarcely likely to be an insect's friend. The term 'pathogen', a legitimate description of the characteristic effects of the particles, becomes an assertion of their absolute nature. Disease-production becomes inherent in the particle itself, as though it were not the changing relations of viruses with plants, insects and the rest of their environment which produce disease, but the viruses themselves, as Bawden has objected. Plant and insect then provide only contingent circumstances, the one a mere culture medium, the other a mere inoculation needle ; and if material things are not to be understood in their relation to their material environment, then they cannot be understood at all, except by invoking entelechies.

Of course, few virus workers, and least of all those concerned with physico-chemical characterization, would regard this as the logic of their work. Others may see it more easily, just as Schrödinger[30], who is not a biologist, sees the vitalist logic of another particulate theory, the gene theory of heredity. Particulate theories have played a large part in the history of biology, as of other sciences, because discontinuities do exist in Nature, which is mere confusion until they are discovered, and it may take a long time before further work corrects the assumption that they are absolute. Particles exist; but disappointment always follows if they are *in themselves* held responsible for the properties of the whole which is being analysed. Particles so self-sufficient that they have no necessary, but only contingent, relations are mystical particles. This is implicit in every particulate theory from the beginning, and the sooner it is recognized the less difficult is the inevitable abandonment of the theory when, as now in virus research, facts which contradict it begin to appear.

SULPHUR FROM SEA WATER

By Prof. HUGH NICOL

West of Scotland Agricultural College, Glasgow, C.2

EVERY informed person will agree that the present stage of manufacturing industry is wasteful and cannot be viewed as other than a phase of civilization. The United States is taking thought about a shortage of water, which is being run into the sea more rapidly than it can be collected on land. The length of time that some world natural resources can be expected to last varies greatly: it is possibly a thousand years for raw phosphate, and perhaps a couple of generations for the sulphur ores collectively. Utilization of renewable supplies of raw materials must sooner or later become important. Two adaptations suggest themselves in this connexion: greater use of microbes and of products from the sea.

There is a case for regarding many inorganic raw materials, including sulphur, as microbial products or fossils[1]. There seems to be small hope of utilizing autotrophic organisms, excepting green plants; and conscious utilization of contemporary microbes must turn upon getting them to act upon organic material, wherefore sources of organic matter require consideration. With shortage of land and of food there is little scope for applying products of the soil, except possibly sulphite liquor (presuming sufficient supplies of sulphur) and sewage sludge. Neither of these is generally available.

Not only manufacturing industry will suffer from a shortage of sulphur: a more serious threat is to the supply of high-class protein, since the method of choice for making rock phosphate available to plants has involved use of sulphur, and other modes all involve increased consumption of fuel or power. For high yields of meat, dairy products, and eggs, there is no simple alternative to the association of leguminous plants, grass, and phosphate, which is essentially an intensive development of the past fifty years[2]. The characteristic function of nitrogenous manures is to yield non-nitrogenous constituents of plants[2,3].

Almost sixty years ago the interest in marine chemistry was great enough to render the idea of biological reduction of sulphates familiar to a few. Some remarkable work was done in Scotland; and the Odessa Bacteriological Station not only showed that at least in its depths the Black Sea is a vast lake of hydrogen sulphide solution[4], but also brought to light a bacillus able to produce hydrogen sulphide from sea water[5]. The summer smells of the Dutch canals induced Beijerinck to investigate a problem which lay literally at his doorstep in Delft, and in 1895 he described many characters of a bacterium able to reduce sulphates in polluted fresh water[6]. The microbiological work was extended by van Delden[7], and a similar organism was isolated from the sea; and Baars[8] broadened the concept of the sulphate radical as oxidizing agent, by showing that in presence of a suitable bacterial 'catalyst' a sulphate can be used, for example, to oxidize ethyl alcohol to acetic acid when the necessary oxygen is derived only from sulphate and water. From all this work it appeared that almost any kind of organic matter could be utilized by the bacteria engaged in sulphate-reduction, provided the carbon/nitrogen ratio of the medium were made small enough.

During the early stages of these developments in formal bacteriology, a series of events was occurring which can now be seen to have great significance in relation to production of sulphur from sea water. These instructive events were nuisances arising from pollution of British estuaries after discharge of sewage into them, in particular, near Belfast and Dublin. The occurrences were investigated by Letts and Adeney[9]; and although most of their attention was given to Belfast Lough, the findings at Dublin were additionally significant in showing the close connexion between discharge of sewage and 'spontaneous' growth of seaweed, particularly *Ulva latissima*.

The nuisance was largely due to release of sulphuretted hydrogen. Letts and Adeney made many experiments with the view of ascertaining the conditions leading to production of that gas. Bacteriological chemistry was not then sufficiently developed to offer the guiding principles we now have. The work of Letts and Adeney derives current importance less from the painstaking laboratory experiments than from their field observations. These are reasonably well known to sewage chemists, but have had little or no impact on other specialists whose co-operation is necessary for an appreciation of the facts revealed.

Points pertinent to the involuntary demonstrations at Belfast and Dublin are: (1) given organic matter, there is no difficulty in principle in inducing bacteria to produce hydrogen sulphide from sea water; (2) the chief value of sewage in this connexion is as a source of nitrogen and phosphate; these conduce to growth of weed, which provides a large bulk of organic matter *in situ*; (3) seaweed can contribute inorganic and organic sulphates in proportions together much greater than the proportion of sulphate in sea water; it probably also contains reducible organic sulphur; (4) no special cultivation of bacteria or seaweed is necessary; both will arise 'spontaneously' as elective cultures if appropriate nutrients and conditions are provided.

To point out these facts is not to suggest that an addition of sewage or of seaweed to sea water kept anaerobic will lead to production of hydrogen sulphide as easily as by adding acid to an alkaline sulphide. Work by Irvine and Gibson[10], for example, did suggest that to produce hydrogen sulphide from sea water to which a fragment of decomposing mussel flesh had been added was almost as easy as that, though a few days incubation was required. There is, however, much chemical difference between any seaweed and the other forms of organic matter used by workers in the field of sulphate-reduction. Unless the right conditions are offered for sulphate-reduction by seaweed, anaerobic digestion of weed may lead to a methane fermentation or other type in which hydrogen sulphide is not prominent.

Without wholly accepting the view of Letts and Adeney that decomposition of seaweed proceeds in two stages, it will be clear that the seaweed must undergo a preliminary microbial decomposition (of unknown nature and extent) before it can serve as source of organic matter for reduction of its own sulphates and those of sea water; other factors such as temperature, species of weed, and the ratio of seaweed to sea water are important, and their elucidation must require considerable laboratory work.

Neither the series of occurrences at Belfast and Dublin nor the laboratory work performed hitherto has done much to indicate optima for commercial production of sulphur from sea water. What the estuarial phenomena of c. 1900 did was to show that hydrogen sulphide can be released from the sea to any desired extent. These repeated large-scale demonstrations are very little known in spite of their now topical interest.

The engineering difficulties in collecting the evolved gas appear formidable; but there seems to be no relevant biological or chemical problem that cannot be tackled by present technique, and the production of sulphur from sea water by biological means may well be the easiest to solve of the future problems of supply of raw materials to industry.

The ecological chain is at least as interesting as the connexion alleged by Darwin to exist between spinsters and red clover. Sewage is not essential, and might be replaced by, say, nitro-superphosphate. Thus a roundabout route would be opened for inorganic nitrogen to be converted (so to speak) into protein for human consumption, via sulphur, phosphate, clovers, and grazing animals. The existing routes are also expensive in labour and in money, since they either depend upon mechanical cutting and processing in place of grazing, or upon expenditure to supplement or replace bacterial fixation of nitrogen from which most of our high-class protein-nitrogen comes[3]: this costs nothing except for earthy materials such as phosphate, potassium, calcium, and sulphur, which must in any event be provided. The spread of synthetic fixation of nitrogen has left the fundamentals of plant growth and protein production unaltered, and nothing could be more wrong than to imagine that agricultural application of 'synthetic nitrogen' has been a victory for the factory over biology. Putting industrial fixation of nitrogen from the air to aid sulphate-reducing bacteria in the sea may be of the type of things to come.

OBITUARY

Prof. Otto Meyerhof, For.Mem.R.S.

OTTO MEYERHOF, who was born at Hanover on April 10, 1884, died at Philadelphia on October 6, 1951.

He began his scientific career with the study of medicine and at first was interested in psychology and psychiatry. But, particularly under the influence of his friend, Otto Warburg, he turned to physiology and biochemistry; indeed, they collaborated in a paper on the part played by cell structure in metabolism—a paper describing for the first time the application of manometric methods to respiration measurements. After he had settled in Kiel (where he went in 1912) he began the magnificent series of papers on the biochemistry of contraction of intact, isolated muscle. Like Hopkins, he felt muscle to be the material *par excellence* for study of the correlation of function and metabolism in living tissue.

Setting out from the fundamental observations of Fletcher and Hopkins and their collaborators at Cambridge, Meyerhof made a wide and exact survey of the relations of lactic acid and glycogen content, oxygen uptake, and heat and tension production in a variety of conditions. He showed for the first time the close proportionality of production of tension and lactic acid formation in anaerobic contraction; but perhaps his most important findings were concerned with oxidative recovery. Here he showed that, of the lactic acid disappearing, the equivalent of some four-fifths reappears as glycogen while the oxygen uptake accounts for complete oxidation of the remainder. Furthermore, the heat production corresponds to only one-half of that to be expected from this oxidation, so that part of the energy is retained for synthetic purposes.

This series of papers was not published until after the end of the First World War and reached Great Britain only in the early months of 1921. The excitement of their urgent translation in Hopkins' laboratory at Cambridge is a vivid memory, as well as the intense satisfaction derived from the flood of light they threw on problems continually discussed there.

Meyerhof went on for some time with his work on the whole muscle, especially in efforts to balance the observed heat production with that to be expected from the known chemical changes. Very accurate measurements gave always a deficit in the latter figure, and this was explained only after the discovery of creatinephosphate.

In 1926, two years after his move to the Kaiser Wilhelm Institute for Biology at Berlin-Dahlem, he began the work on enzymically active muscle extracts which, continued with several collaborators, was to prove so fruitful. Working with these extracts and with extracts from yeast, he followed up and extended the perspicacious but largely unproved suggestions of Gustav Embden, bringing to light new enzymic stages in carbohydrate breakdown and preparing hitherto unknown intermediates.

In 1927 the discovery of creatinephosphate and the observation (first by the Eggletons and by Fiske and SubbaRow, and then in his own laboratory) of its breakdown during contraction and resynthesis during recovery raised difficulties for the lactic acid theory of contraction. This was felt especially in two facts: first, that while creatinephosphate breakdown is a markedly endothermic reaction and while the breakdown was known to occur chiefly in the early stages of contraction, experiment so far had seemed to show proportionality between lactic acid production and heat formation; secondly, that the anaerobic resynthesis of creatinephosphate was not accompanied by heat absorption. Meyerhof at this time made an error of scientific judgment, rare for him, in his reluctance to admit the part played by creatinephosphate breakdown in contraction, apparently inclining towards the suggestion that the breakdown might not be happening *in vivo*, but was an artefact due to the treatment of the muscle in extraction. He failed, too, to attach importance to the findings of post-relaxation lactic acid formation by the Embden school. However, his experiments with Lipmann, published early in 1930, concerning the *p*H changes upon stimulation of intact muscle, left him in no doubt about the reality of creatinephosphate breakdown, and in the same year he was ready to welcome the results of Lundsgaard on iodoacetate-poisoned muscle with their clear implication that creatinephosphate breakdown is a stage nearer the muscle machinery than is lactic acid formation. He invited Lundsgaard to continue his work at Heidelberg, and the problems mentioned above were solved by combined work there.

Meanwhile Lohmann, in Meyerhof's laboratory, had made the discovery of adenosinetriphosphate in 1929, and during the 1930's Meyerhof's laboratory, together with others in Lwow, Cambridge and Berlin, cleared up the problems of the co-enzyme function of the adenylic compounds and laid the foundations for the understanding of the part played by these compounds in energy transfer. The unique contribution of the Meyerhof school here was the investigation of the heat of reaction of various stages in glycolysis and of the heat of hydrolysis of creatinephosphate, argininephosphate (a compound discovered in invertebrates by Meyerhof and Lohmann), adenosinetriphosphate and phosphopyruvic acid. Such studies led to the early realization of the important difference in nature between the phosphate bond in these compounds and in the ordinary ester linkage.

Although he was during these years mainly concerned with isolated enzyme systems, Meyerhof still turned to the muscle as a whole, for example, in the work with Möhle and Hartmann on volume changes accompanying contraction.

In 1924 he had become head of the Department of Physiology in the Institute for Medical Research in Heidelberg and remained there until 1938. One of his research workers in the latter part of this period has described his daily round, discussing without any dictatorial attitude, but with complete grasp of detail in each case, the results of yesterday and the programme for to-day. This collaborator has written: "The daily round took him from worker to worker, Japanese, French, English, Italian, Spanish, American, German. It was a stimulating event and lingered on in one's mind. The thoughtfulness of the faces of the people in the room is strongly in my memory." Meyerhof himself worked in the laboratory daily and one striking characteristic was his prodigious memory for facts and figures. He loved to show a very generous hospitality to his colleagues.

It has been said of him that his intense and single-minded concentration on the pursuit of scientific truth shut him off as behind an intangible curtain from current events. This concentration made it possible for him to stay on in Heidelberg for five years after the rise of the Nazis, without loss of personal dignity and integrity. He even during this time accepted at least one new Jewish worker, refusing to consider the possibility of outside interference with the conduct of his laboratory. But by 1938 the situation had become impossible and Meyerhof, like other scientific men of Jewish origin, was obliged to leave Germany. He was welcomed in Paris and went on with his work at the Institut de Biologie Physico-Chimique until the invasion of 1940. With the help of the Rockefeller Foundation and of friends in America, he and his wife were able to reach the United States, and he was appointed research professor of physiological chemistry in the University of Pennsylvania. His reputation was, of course, international; he had shared the 1922 Nobel Prize for physiology with A. V. Hill, and among many other honours had been elected in 1937 a foreign member of the Royal Society. After his exile he did much to help in the re-establishment of displaced scholars less well known abroad.

From 1938, Meyerhof's scientific work was concerned mainly with enzyme studies, and he devoted much attention to questions of the free-energy content of phosphorylated compounds. He continued to break new ground, as in his study with H. Green of the transphosphorylating activity of intestinal phosphatase.

An aspect of Meyerhof's interests which remained less well known to his colleagues, at least in other countries, was his work on the history and philosophy of science. He was an authority on Goethe's scientific contribution; and in 1933 he published an excellent lecture on theoretical biology in which he adopted a point of view allied to the Whiteheadian doctrine of organism, in general agreement with the biological implications which Woodger had set forth a few years before. He had a great love, too, for painting and for literature.

Such were some of the achievements and activities of one of the greatest of biochemists.

Dorothy Needham

NEWS and VIEWS

Royal Society : Medal Awards

H.M. THE KING has been graciously pleased to approve recommendations made by the Council of the Royal Society for the award of the two Royal Medals for the current year as follows :

Sir Howard Florey, professor of pathology in the University of Oxford, for his distinguished contributions to pathology by his studies of the functions of mucin and by his work on penicillin and other antibiotics ;

Sir Ian Heilbron, director of the Brewing Industry Research Foundation, for his distinguished contributions to organic chemistry, notably in the field of vitamin A and polyene synthesis.

Nobel Prize for Physics : Sir John Cockcroft, C.B.E., F.R.S., and Prof. E. T. S. Walton

THE award of the Nobel Prize for Physics for 1951 jointly to Sir John Cockcroft and to Prof. E. T. S. Walton will be warmly welcomed not only by nuclear physicists but also by many others. The disintegration of elements by artificially accelerated protons was announced by Cockcroft and Walton from the Cavendish Laboratory, Cambridge, in 1932, after some years of research into methods of producing high-velocity positive ions. This work was encouraged from the start by Lord Rutherford with the specific object of obtaining a more intense source of projectiles for nuclear transmutation experiments than was provided by the alpha-particles from natural radioactive bodies. The apparatus finally used by Cockcroft and Walton developed a steady potential of about 600,000 volts and supplied currents of about 5 microamperes of hydrogen ions. The impact of these high-velocity ions on targets of light elements, notably lithium and boron, produced a copious yield of alpha-particles which were detected by scintillation screens and the measured energies of which showed that they came from nuclear transmutations. The original tube and a model of the whole apparatus are in the Science Museum, South Kensington.

The immediate importance of these experiments apart from the popular appeal of success in splitting the atom) was that they confirmed Gamow's theory of barrier penetration, according to which nuclear disintegrations might be produced by light particles of relatively low energy. The way to the study of a great variety of nuclear reactions was thus thrown open, and with the successful application elsewhere of the cyclotron and electrostatic generator in similar work, a rapid expansion of experimental nuclear physics took place. The work of Cockcroft and Walton did not in itself reveal any new fundamental properties of nuclear structure ; but it stimulated many theoretical and technical developments and thereby inevitably influenced the whole course of nuclear physics. In a narrower field it laid the foundations of the precise study of energy changes in nuclear reactions induced by charged particles. It is only fitting that the highest honour should be paid to work which has so fully the character of a pioneer investigation, in that it has been eagerly seized on and extended by others and that it is an acknowledged landmark in the history of science.

Nobel Prize for Chemistry : Profs. E. M. McMillan and G. T. Seaborg

THE award of the Nobel Prize for Chemistry for 1951 to Profs. E. M. McMillan and G. T. Seaborg directs the attention of the whole scientific world to the most spectacular advance made in inorganic chemistry for a long time, the extension of the Periodic System from element 92, uranium, to element 98, californium. Speculations about the possible existence of trans-uranium elements are old : they could not be found in Nature ; but as soon as E. Fermi and his collaborators in Rome had detected the transmuting power of slow neutrons, they applied it to uranium and seemed to obtain in this way an element higher up in the Periodic Table. These researches were continued in Paris and Berlin, and for several years it was believed that four or five successive trans-uranium elements could be synthetized by this simple method, until O. Hahn and F. Strassmann recognized that these newly formed nuclides were nothing but isotopes of well-known elements produced by the process of 'fission'. The first real trans-uranium element, of atomic number 93, was identified by E. M. McMillan and P. Abelson early in 1940. From then on progress was rapid. With the help of powerful cyclotrons and the newly constructed uranium piles, a large team of workers concentrated on the task of producing isotopes, and of studying the properties, of the elements 93 (neptunium), 94 (plutonium), 95 (americium), 96 (curium), 97 (berkelium) and 98 (californium). These researches were greatly helped by the ample means put at the disposal of the investigators in view of the great practical importance of their investigations ; it is well known that one of the trans-uranium elements, plutonium, provided the material for one kind of atomic bomb, and that it will, one hopes, soon be put to peaceful use in the operation of power plants. The award of the Nobel Prize for Chemistry to a physicist, McMillan, and a chemist, Seaborg, both of the University of California, singles out the two most outstanding names in a group of excellent research workers, and is a tribute to a type of research organization which nowhere has been brought to such perfection as in the big scientific laboratories of the United States.

Mathematics at the College of Aeronautics : Prof. G. N. Ward

THE Board of Governors of the College of Aeronautics has created a new post of professor of mathematics in the Department of Aerodynamics, and Mr. G. N. Ward, senior lecturer in mathematics in the University of Manchester, has been appointed to the chair. Prof. Ward was at St. Catharine's College, Cambridge, where he obtained first-class honours in the Mechanical Sciences Tripos. During the early part of the Second World War he worked in the Admiralty on problems involving the study of geomagnetic deviations, very-low-frequency circuits, and ultrasonics. Later he was transferred to the Engineering Division of the National Physical Laboratory, where he studied experimental and theoretical supersonic flow and designed the earliest British supersonic guided missile. Gradually he leaned more to the theoretical side of the work, and played an important part in the years following the War in building up the very extensive body of solutions which now exist to the equations of small perturbations to a supersonic stream, a field of study both of great practical importance and theoretical interest and complexity. His essay on the subject submitted in 1950 for the Adams Prize of the University of Cambridge was awarded an honourable mention. His best-known papers in the field refer to perturbation by nearly cylindrical ducts, by slender bodies of arbitrary cross-section bearing wings of small aspect ratio, and by thin wings of intermediate aspect ratio. He is particularly interested in the teaching of mathematics to engineers in such a way that they may be enabled to make full use of it in their work.

Bird Exploration Fund

THE recent institution of the Bird Exploration Fund is a joint effort by officials of the British Museum (Natural History) and private individuals to fill a need brought about by the economic conditions of present times. The days of private expeditions financed by public-spirited naturalists, which contributed so largely to the study collections of the British Museum, are now past. The importance of scientifically conducted field investigations in conjunction with collecting is widely recognized, and if the knowledge of birds by the collection of specimens is to be extended it is essential that expeditions should be continued. The aim of the newly formed Fund is to make this possible. Vested in trustees and with the official approval of the British Museum, the general purposes of the Fund are stated to be "promoting, organizing and financing in whole, or in part, ornithological expeditions to, and bird explorations in, those parts of the world where bird life is least known". Specimens are to become the property of the British Museum; but collectors who take part in the expeditions will be given every reasonable facility for work and study in connexion with such specimens. It is perhaps not generally realized that public institutions are not readily endowed with private money. The formation of a permanent Fund gives those who wish to forward the science of ornithology an opportunity, by means of their collective support, to make possible these very important expeditions and thereby enrich the national Museum. The headquarters of the Fund are at the Bird Room, British Museum (Natural History), Cromwell Road, London, S.W.7, and all donations and inquiries should be sent to the Secretary-Treasurer.

International Union for the Study of the Behaviour of Social Insects

DURING the Ninth International Congress of Entomology, the termitologists and myrmecologists present decided to set up a permanent international union for the study of the behaviour of social insects. It is intended to approach workers on the social behaviour of insects all over the world and to organize the interchange of ideas and of research programmes from the earliest pre-publication stages, and also to build up a library of reprints for reference purposes. To this end, termitologists and myrmecologists are requested to send not only a complete bibliography of their papers to date, and details of their present projects, but also two reprints of each future paper and of as many past papers as possible. An international address list will also be assembled. It is hoped that it will soon be possible to publish a journal, which at first may be limited to brief notes, but which should eventually cover the field as adequately as possible. At Amsterdam a provisional committee was formed; but a constitutional committee will in due course be elected by the members of the new union. Further information can be obtained from D. Wragge Morley, Organizing Secretary, International Union for the Study of Social Insects, 14*b* Downshire Hill, Hampstead, London, N.W.3.

Medical Research in East Africa

INTERESTING information about the health risks of East Africa is contained in two reports issued by the East Africa High Commission. The annual report for 1950 of the Virus Research Institute (pp. 32, Nairobi: Government Printer, 1951) describes the history of the Institute, its buildings and staff and the work carried out in 1950. The Institute was formerly known as the Yellow Fever Research Institute, having been founded in 1936, and was taken over by the East Africa High Commission in 1950. One section of the report deals with yellow fever and its epidemiology and immunology. A number of sections discuss other viruses, poliomyelitis and rickettsioses, and there is a section on general entomology which includes work on ticks, mosquitoes, ectoparasites of trapped mammals, the biting habits of Tabanidae and studies of the eradication of *Simulium damnosum*. The list of papers published or in the press is evidence of the activity of the staff. The annual report for 1950 of the East Africa Medical Survey (pp. 61; Nairobi: East Africa High Commission, 1951) shows that, in spite of a serious shortage of staff, both laboratory investigations and field surveys have been undertaken in the Mwanza area and on Ukara Island. The results of these are given. A feature of the report is the fact that food is rarely sufficient in quantity and lacks quality women especially suffering because of taboos of important sources of protein. A survey of insect vectors of disease is to be carried out, and an entomologist records his brief survey of the distribution of mosquitoes on Ukara Island. The report also discusses statistics so far available of the maternity histories, reproductive-rate and infant mortality-rate.

Atomic Heating System at Harwell

A BUILDING containing eighty offices at th Ministry of Supply Atomic Research Establishment Harwell, will now draw its heat direct from BEPO the large experimental atom pile. This is the first atomic central-heating plant in the world. Eventually two, and perhaps three, more buildings will also have 'atomic radiators' and the Ministry's coal consumption will be cut by at least a thousand tons a year. Afte counting all incidental expenses, the saving in coal is estimated at £2,650 a year. Costs of the installation amount to £15,000.

The constant hot water which will flow through th pipes is obtained by placing a heat exchanger in th outlet air duct of the pile's air-cooling system. Her there is a by-pass fitted with a damper which can be adjusted to vary the proportion of the air-flow passing through the heat exchanger. Hot water from the exchanger is then circulated in a closed circuit by a small pump to a secondary water-to-water hea exchanger. This supplies hot water for space heating and domestic hot water supplies. At present the ai temperature at the primary heat exchanger is 135° F. and the water itself is heated to 130°. In 1952, when modifications to the pile have been completed, thes temperatures will be substantially increased. Ther is no danger from radioactivity and the water can safely be used for washing. The heat output designe for the first building is one million B.Th.U. per hour equal to about two hundred electric fires; but fo the final installation the maximum output will b seven million B.Th.U. per hour. The total floor area now being heated is 32,000 sq. ft. and the volume of space is 330,000 cu. ft.

History of Coal

"At the Root of it All", a brochure published by the National Coal Board (Public Relations Branch), Hobart House, Grosvenor Place, London, S.W.1 (pp. 32), is the best of the numerous booklets on the British coal industry which have been issued by the Board. It is suitable for general science reading in the upper forms of secondary schools and it should prove interesting to the intelligent layman. It is succinct and factual. The script is by Mr. W. E. Dick, editor of *Discovery*, and the method employed in the booklet is historical, descriptive and statistical. The monochromatic illustrations are good, and a romantic element has been confined to a few coloured plates. The subjects discussed, which have been outlined clearly and accurately, are the formation of coal from decayed vegetation, the improvement of the steam-engine from that of Thomas Savery in 1698, and the uses of coal in the iron and steel industries, for producing electricity and in the home. Short, illustrated sections describe the use of coal in locomotion and the development of lighting by gas. Considerable attention is paid to the by-products of the gas industry: dyes, detergents, disinfectants, antibiotics, insecticides, perfumes, nylon and so on. The booklet ends with a brief account of the mining industry as it has developed, and includes a statement of the sociological aspects and problems of miners. The booklet in its brevity and objectivity is scientific in outlook and is pleasantly free from any political bias. Thus, it admirably fulfils its aim, which is to show the paramount importance of coal in modern living.

United States National Museum: Annual Report for 1949-50

The report of the United States National Museum for the year ending June 30, 1950 (pp. 141; Washington, D.C.: Government Printing Office, 1951), provides interesting reading, and a summary of its activities and acquisitions extending to more than a hundred pages is an indication of the magnitude of the work. This Museum, which is situated in Washington, D.C., and forms part of the Smithsonian Institution, has as its responsibility the classification and preservation of collections, and it is refreshing to note that this and the fundamental policies in general are still recognized. Furthermore, it is recognized that the Museum is not only a storehouse for certain objects but also that its exhibits reveal to the public "the resources of the world in which we live, the material cultures that illustrate the political, cultural and technical achievements of man and the principles that have resulted from scholarly research". These, indeed, are noble aims, and the report indicates how they are put into practice.

Conference on Evolution and Education

The group of organizations interested in the teaching of biology will hold a further joint conference on "Evolution and Education", this time at the Birmingham and Midland Institute, Birmingham, during December 7-8. At the opening session, when Sir Raymond Priestley will preside, Dr. J. B. S. Haldane will deliver an address on "The Evolutionary Process". On December 8, lecture-demonstrations will be given by Miss F. R. Elwell of the B.B.C. broadcast series, "How Things Began", and by Miss E. M. Tuke, on the "Teaching of Evolution". Miss M. Going will speak on "Classroom Problems in Teaching Evolution", with special reference to work in grammar schools. These sessions will be followed by a general discussion, to be opened by Dr. L. M. J. Kramer, over which Mr. W. J. Heasman, H.M.I., will preside. The closing address will be delivered by Prof. S. Zuckerman, speaking on the "Evolution of the Brain". The fee for admission to the conference is 10*s*. Tickets may be obtained from the British Social Biology Council, Tavistock House South, Tavistock Square, London, W.C.1.

British Region of the Biometric Society: Officers for 1952

At the recent annual general meeting of the British Region of the Biometric Society, the following officers and members of committee were elected for 1952: *Vice-President*, Dr. F. Yates; *Treasurer*, Dr. A. R. G. Owen; *Secretary*, Dr. D. J. Finney (6 Keble Road, Oxford); *Members of Committee* (1952-54), Prof. R. A. Fisher and Dr. R. R. Race.

Brazilian Geological Society: Officers for 1951-52

Officers for the term September 1951-November 1952 of the Brazilian Geological Society have been elected as follows: *President*, Prof. O. Barbosa; *Vice-Presidents*, Prof. O. H. Leonardos and Prof. F. W. Lange; *Secretary*, Prof. R. R. Franco; *Treasurer*, Prof. A. F. Barbosa; and *Director of Publications*, Prof. J. C. Mendes. Further details about the Society can be obtained from the Secretary, whose address is Sociedade Brasileira de Geologia, Alameda Glete 463, Caixa Postal 105 *B*, São Paulo.

"Epitaxis of Rubidium Iodide on a Barium Stearate Substrate Deposited on Mica"

Mr. A. A. Fuller writes, with reference to the communication under the above title published in *Nature* of September 15, p. 471: "I was unable to refer, during the course of my experiments, to the *Zeitschrift für Kristallographie*, and so missed reading an account of a series of similar experiments by Dr. R. S. Bradley (*Z. Krist.*, A, 96, 499; 1937). I regret I was therefore unable to mention this work in my communication."

Announcements

Dr. P. B. Treacy, who for three years has been working in the Cavendish Laboratory, Cambridge, has been appointed a Research Fellow of the Australian National University, Canberra, and will work in the Department of Nuclear Physics under the direction of Prof. E. W. Titterton.

The Langley Memorial Prize of the London School of Hygiene and Tropical Medicine has been awarded to Dr. J. H. Gerber, medical officer in charge, Endemic Diseases Control Unit, Kailahun, Sierra Leone, for his paper on "Bilharzia in Boajibu". This Prize is awarded by the School triennially for the best paper written by a member of the West African medical staff on tropical medicine and surgery, hygiene, entomology or parasitology.

Erratum. In Table 1 of the communication "C_{20-22} Unsaturated Acids of Butterfat" in *Nature* of July 14, p. 75, Sample *A*1, for "sap. equiv. 338·3" read "sap. equiv. 318·3".

SYNTHESIS OF POLYACETYLENIC COMPOUNDS

By Prof. E. R. H. Jones, F.R.S., Dr. M. C. Whiting, Dr. J. B. Armitage, Dr. C. L. Cook
and Dr. N. Entwistle

Chemistry Department, University of Manchester

DURING the period 1927–38, Kuhn and his co-workers[1] synthesized a wide range of conjugated polyethenoid hydrocarbons, and by correlating light-absorption properties with constitution, they not only provided a rational basis for the interpretation of the chemistry of the carotenoids, but also stimulated much fruitful discussion about the fundamental nature of conjugated systems and their photochemical excitation[2]. Recently it has become possible to prepare similar compounds in which the terminal groupings are separated by a chain of conjugated acetylenic, rather than ethylenic, linkages, the comparison of which with the corresponding polyenes is of obvious interest.

In this work our aims were to obtain these substances, including when possible the higher members of each series, by convenient methods, and to characterize them as fully as their stability permits. When the widespread natural occurrence of di- and tri-acetylenic compounds, in essential oils from species of Compositæ[3], in the seed-fat of *Onguekoa Klaineana* Pierre[4], and some Basidiomycetes[5], became evident, the programme was modified to include the preparation of fairly close analogues of some of these. The recent appearance of publications along similar lines[6], and the interest of these substances to the biochemist and, because of their linear structure and consequent simple geometry, to the theoretical chemist, make it desirable to summarize our results at this stage.

The reaction sequences employed fall into two classes. In the first a glycol is converted by reaction with thionyl chloride and pyridine into a dichloride, which on dehydrochlorination with sodamide in liquid ammonia gives a hydrocarbon containing one triple bond more than the starting material. In the special case where the original glycol is di-primary, the product, a hydrocarbon $H(C{\equiv}C)_nH$, may be converted by an excess of sodamide to a disodium derivative, which can then react *in situ* with an alkyl halide or with a carbonyl compound. If formaldehyde is used, such a sequence of reactions formally permits an indefinite progression, one triple bond being added at each stage, and this has to some extent been realized:

$$\begin{array}{l}
HOCH_2.C{\equiv}C.CH_2OH \xrightarrow{SOCl_2,Py} \\
ClCH_2.C{\equiv}C.CH_2Cl \xrightarrow{NaNH_2,H.CHO} \\
HOCH_2.C{\equiv}C.C{\equiv}C.CH_2OH \xrightarrow[NaNH_2,H.CHO]{SOCl_2,Py} \\
HOCH_2.C{\equiv}C.C{\equiv}C.C{\equiv}C.CH_2OH.
\end{array}$$

In the second class the series is ascended more rapidly; a monosodium derivative is obtained by the action of three molecules of sodamide on a diprimary dichloride, then a monosubstituted poly-yne or a poly-yne carbinol is prepared by condensation with one molecule of an alkyl halide or a carbonyl compound, and the oxidative coupling reaction employed to convert $R.(C{\equiv}C)_n.H$ to $R.(C{\equiv}C)_{2n}.R$. Alternatively, a monosubstituted diacetylene may be obtained as described above from a primary–secondary glycol, $R.CH(OH).C{\equiv}C.CH_2OH$, prepared by a Grignard reaction between an aldehyde and the *bis*-bromomagnesium derivative of propargyl alcohol.

By suitable combinations of these methods a range of dimethylpoly-ynes (I; $n = 2, 3, 4, 5$ and 6) has been synthesized.

$$\underset{\text{I}}{CH_3.(C{\equiv}C)_n.CH_3} \qquad \underset{\text{II}}{Me_2C(OH).(C{\equiv}C)_n.C(OH)Me_2}$$

$$\underset{\text{III}}{Ph.(C{\equiv}C)_n.Ph}$$

The first is well known, and the next two were briefly described in October 1949[7]; recently another synthesis of (I; $n = 4$) has been published[8a]. The hydrocarbons (I; $n = 5$ and 6) were prepared as indicated below:

$$\begin{array}{l}
CH_3.CHO \xrightarrow{NaC_4H} CH_3.CH(OH).(C{\equiv}C)_2H \xrightarrow{CuCl,O_2} \\
CH_3.CH(OH).(C{\equiv}C)_4.CH(OH).CH_3 \xrightarrow{SOCl_2,Py} \\
CH_3.CHCl.(C{\equiv}C)_4.CHCl.CH_3 \xrightarrow{NaNH_2} (I;\ n = 5) \\
HOCH_2.(C{\equiv}C)_2.CH_2OH \xrightarrow{SOCl_2,Py} \\
ClCH_2.(C{\equiv}C)_2.CH_2Cl \xrightarrow{NaNH_2,MeI} \\
CH_3.(C{\equiv}C)_3H \xrightarrow{CuCl,O_2} (I;\ n = 6).
\end{array}$$

All are crystalline solids, which (except $n < 4$) decompose below their melting points and were crystallized until their ultra-violet absorption spectra were constant. They are not dangerously explosive, and (I; $n = 4$) may even be sublimed at 50°/10^{-3} mm. Those members with $n > 3$ are very easily decomposed by light, but in the dark, or in solution even in the presence of light, they are much more stable; storage at −70° is desirable, but all can be crystallized from warm solvents.

A series of glycols of type (II) has also been obtained, using related methods; those with $n = 2$, 3, 4, 5 were isolated as crystalline solids, appreciably more stable than the dimethylpoly-ynes. The glycol (II; $n = 6$) was also prepared; but a 10 per cent concentrate could not be further purified. Many glycols of other types, especially $HOCH_2.(C{\equiv}C)_n.CH_2OH$ and $CH_3.CH(OH).(C{\equiv}C)_n.CH(OH).CH_3$, have also been made; the primary and secondary glycols are very much less stable than the corresponding tertiary glycols. The dichloride $ClCH_2.(C{\equiv}C)_4.CH_2Cl$, an intermediate in the preparation of (II; $n = 5$), is the compound most sensitive to light yet encountered in this field; it surpasses silver bromide in this respect, becoming dark blue on exposure to diffused daylight for 10–30 sec.

For the preparation of the diphenylpoly-ynes the obvious extension of one of the routes employed for the dimethyl compounds succeeded for (III ; $n = 3$), easily prepared from benzaldehyde by a route independently used by other workers[4a,4c]:

$$\begin{tikzcd}
\mathrm{Ph.CH(OH).(C{\equiv}C)_2.CH(OH).Ph} \arrow[r, "\mathrm{SOCl_2,Py}", "\mathrm{NaOEt\ or\ NaNH_2}"'] & \mathrm{(III\ ;}\ n = 3\mathrm{)} \\
\mathrm{Ph.CHO} \arrow[u, "\mathrm{NaC{\equiv}CH,\ CuCl,O_2}"'] \arrow[d, "\mathrm{BrMgOCH_2.C{\equiv}CMgBr}"'] & \\
\mathrm{Ph.CH(OH).C{\equiv}C.CH_2OH} \arrow[r, "\mathrm{SOCl_2,Py}", "\mathrm{NaNH_2}"'] & \mathrm{Ph.C{\equiv}C.C{\equiv}CH} \arrow[d, "\mathrm{CuCl,O_2}"] \\
 & \mathrm{(III\ ;}\ n = 4\mathrm{)}
\end{tikzcd}$$

The next member, (III ; $n = 4$), was obtained by the route shown; the phenylbutadiyne was also (but less conveniently) prepared from phenylbutadiene tetrabromide, a method independently used by Schlubach and Franzen[4e], and isolated as a low-melting solid.

For the preparation of (III ; $n = 6$), α-bromocinnamaldehyde was condensed with propargyl alcohol to give a crystalline glycol, readily converted to the dichloride (IV).

$$\underset{\mathrm{IV}}{\mathrm{Ph.CH{=}CBr.CHCl.C{\equiv}C.CH_2Cl}} \xrightarrow{\mathrm{NaNH_2}} \mathrm{Ph.(C{\equiv}C)_3H} \xrightarrow{\mathrm{CuCl,O_2}} \mathrm{(III\ ;}\ n = 6\mathrm{)}$$

The latter gave, after dehydrohalogenation and oxidative coupling, a surprisingly high (30 per cent) overall yield of the hexa-yne (III ; $n = 6$). This is a beautifully crystalline substance (orange needles) which is not photosensitive in the solid state and is therefore easier to handle than (III ; $n = 4$) or the aliphatic poly-yne hydrocarbons. It was fully characterized by analysis and quantitative hydrogenation.

[*Added in proof*. October 18. Since this manuscript was submitted, diphenylocta-acetylene (III ; $n = 8$) has been obtained by a process essentially similar to that employed for the preparation of (III : $n = 6$), penta-2 : 4-diyne-1-ol, being employed in place of propargyl alcohol. The photosensitive octa-yne, which forms red needles, cannot be kept undecomposed for more than a few hours at 20°, even in the dark. Two samples exploded on attempted analysis, but with a third it was possible to obtain some approximate analytical data (found: C, 95·3 ; H, 2·85 ; $C_{28}H_{10}$ requires C, 97·1 ; H, 2·9 per cent). However, light absorption data quoted below provide unequivocal evidence for the assigned structure.]

The naturally occurring polyacetylenes frequently possess ethylenic linkages in conjugation with a poly-yne chain, and often carboxyl groups as well; thus Sörensen[3d,8] has isolated from *Artemesia vulgaris* L. a compound with the structure

$$\mathrm{CH_3.CH{=}CH.C{\equiv}C.C{\equiv}C.C{\equiv}C.CO_2Me}$$

('dehydromatricaria ester').

The synthesis of model substances possessing these features was therefore attempted. Vinyl- and propenyl diacetylenes were obtained in good yield by the following route (R = H or CH_3). The anionotropic rearrangement[9] in the chlorination reaction (incomplete when R = H) and the modification in the dehydrohalogenation reaction therefore required are noteworthy.

$$\begin{aligned}
&R\mathrm{.CH{=}CH.CHO} \xrightarrow{\mathrm{BrMgC{\equiv}C.CH_2OMgBr}} \\
&R\mathrm{.CH{=}CH.CH(OH).C{\equiv}C.CH_2OH} \xrightarrow{\mathrm{SOCl_2,Py}} \\
&R\mathrm{.CHCl.CH{=}CH.C{\equiv}C.CH_2Cl} \xrightarrow{\mathrm{NaNH_2}} \\
&\underset{\mathrm{V}}{R\mathrm{.CH{=}CH.(C{\equiv}C)_2H.}}
\end{aligned}$$

The light-absorption properties of (V ; R = Me) proved to be very similar to those recorded by Castille[4] for erythrogenic or isanic acid, present in the glycerides of boleko nuts (*Onguekoa klainea* Pierre). These are now known to exclude the possibility that his compound had one of the structures (VI) which he suggests, since vinylacetylenes absorb intensely at ∼ 2230 A. (ε = 12,000)[10]. They are compatible with the hypothesis that Castille's acid was a mixture of c. 5 per cent of a C_{18} acid possessing a —CH=CH.C≡C.C≡C— grouping, and 95 per cent of (VII) (which would show light-absorption of relatively low intensity), the alternative structure suggested by oxidative degradation[4]. The former acid has recently been isolated by Dr. E. M. Meade[5].

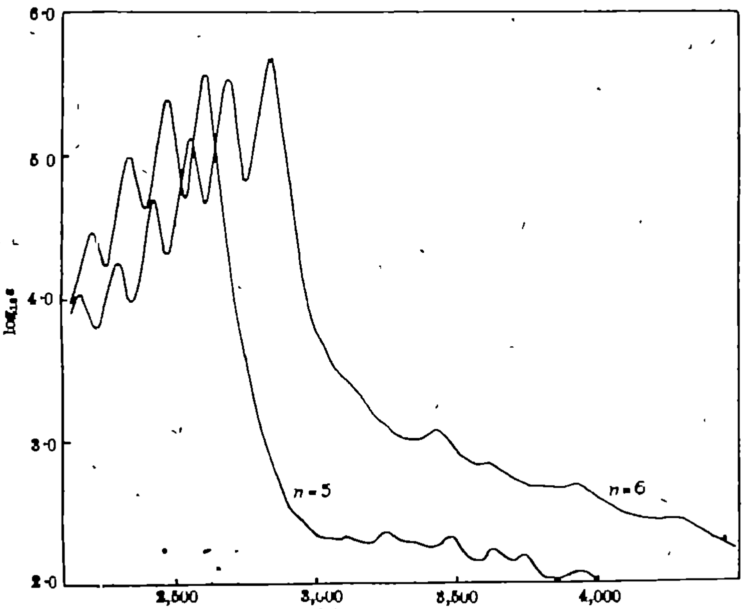
$$\underset{\mathrm{VI}}{\mathrm{H_2C{=}CH.C{\equiv}C.(CH_2)_4.C{\equiv}C.(CH_2)_7.CO_2H}}$$

$$\underset{\mathrm{VII}}{\mathrm{H_2C{=}CH.(CH_2)_4.C{\equiv}C.C{\equiv}C.(CH_2)_7.CO_2H}}$$

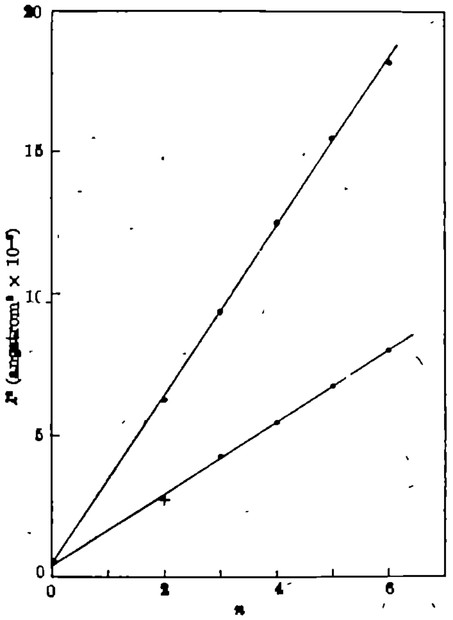
Oxidative coupling of (V, R = Me) gave (VIII ; $n = 4$); the lower members of this series have also been obtained, the diyne in two stereo-isomeric forms by oxidative coupling of the *cis*- and *trans*-forms of pent-3-en-1-yne[11], and the triyne by the route:

$$\begin{aligned}
&\mathrm{CH_3.CH{=}CH.CH(OH).C{\equiv}CH} \xrightarrow{\mathrm{CuCl\ O_2}} \\
&\mathrm{CH_3.CH{=}CH.CH(OH).(C{\equiv}C)_2.CH(OH).CH{=}CH.CH_3} \\
&\qquad\qquad \xrightarrow{\mathrm{SOCl_2,Py}} \\
&\mathrm{CH_3.CHCl.CH{=}CH.(C{\equiv}C)_2.CH{=}CH.CHCl.CH_3} \\
&\qquad\qquad \Big\downarrow \mathrm{NaNH_2} \\
&\qquad\qquad \mathrm{(VIII\ ;}\ n = 3\mathrm{).}
\end{aligned}$$

This latter (crystalline) hydrocarbon has an ultraviolet absorption spectrum almost superimposable on that of a liquid hydrocarbon isolated from *Artemesia vulgaris* L.[3d], which is possibly the *cis–cis* form of (VIII ; $n = 3$).



Light absorption of (I ; n = 5 or 6)



Light absorption of (I ; n = 2–6).

IX X

On treatment with carbon dioxide, the Grignard derivatives of penta-1 : 3-diyne and hepta-1 : 3 : 5-triyne gave the crystalline acids (IX ; $n = 2$ and 3) ; while the derivatives of diacetylene and hexatriyne similarly yielded the acids (X ; $n = 2$ and 3), the former being obtained in quantity. Re-investigation of Baeyer's claim[11] to have prepared the highly unstable acid (X ; $n = 4$) has indicated that the reactions he employed do indeed lead to the formation of some of this substance, which the original work did not establish.

Light-Absorption Properties

The ultra-violet absorption spectra of the compounds prepared show many points of interest. In every case well-defined fine-structure was observed, the maxima showing a spacing of 2,000–2,300 cm.$^{-1}$ as compared with the typical polyene fine-structure spacing of ~ 1,600 cm.$^{-1}$. This provides an easy method of recognizing polyacetylenic groupings, for example, among the extracts of Compositæ examined by Sörensen *et al.*[8] and in the antibiotics nemotin, nemotinic acid, nemotin A and agrocybin[9].

In the case of dialkylpoly-ynes (the spectra of the highest members of the series are reproduced here) the most noteworthy feature is the very high intensity of absorption at short wavelengths ; (I ; $n = 6$) has $\epsilon_{max.} = 445,000$ at 2840 A., easily the highest molecular extinction coefficient yet recorded. Indeed, if the absorption intensity per unit weight (as E(1 per cent, 1 cm.)) is considered, the dimethylpoly-ynes exceed all other substances by a factor approaching 3 ((I ; $n = 6$) has E(1 per cent, 1 cm.) = 25,500 ; anthracene has (at 2510 A), E(1 per cent, 1 cm.) = 9,400, the highest value which could be found). In this region the highest maxima have molecular extinction coefficients approximating to 72,000 n, whereas the polyenes do not exceed 18,000 n.

The variation of $\lambda^2_{max.}$ with n in the dimethylpoly-ynes is illustrated below both for the first of the ultra-high-intensity bands and for the first of the medium-intensity ($\epsilon \sim 200$) bands observed at longer wave-lengths. An accurately linear relationship is observed in each case.

[*Added in proof.* October 18. Diphenyloctaacetylene (III ; $n = 8$) in ethyl acetate solution exhibited the following maxima : $\lambda_{max.}$A. 2440, 2595, 2740, 3040, 3220, 3415, 3580, 3760, 4300, 4660 and 5090 ; $\log_{10}\epsilon$ 4·42, 4·38, 4·49, 5·00, 5·36, 5·48, 5·40, 5·17, 4·09, 3·98 and 3·95 respectively.]

The ultra-violet absorption spectra of the other polyacetylenic compounds prepared will be discussed in later publications, along with infra-red spectra, but a list is given below of those of some of the

THE HYPERGLYCÆMIC ACTION OF BLOOD FROM ANIMALS TREATED WITH GROWTH HORMONE

By Dr. J. BORNSTEIN*

Dept. of Chemical Pathology, King's College Hospital, London

Dr. E. REID† and Prof. F. G. YOUNG, F.R.S.

Dept. of Biochemistry, University of Cambridge

THE alloxan-diabetic-hypophysectomized-adrenalectomized rat (ADHA rat) can be used for the assay of insulin in blood[1]. Since growth hormone is diabetogenic in intact[2] or partially depancreatized[3] animals of some species, the insulin content of the blood of animals treated with growth hormone was of some interest. Bornstein[4] found in preliminary experiments that the blood of ADHA rats treated with growth hormone not only failed to exhibit an insulin-like action in recipient ADHA rats, but also induced a rise of blood sugar in the recipient animals. The rat is one species of animal which does not, in the intact state, become diabetic when treated with growth hormone. In view of the results of these preliminary experiments, it was of interest to determine whether blood obtained from cats treated with growth hormone, which were either diabetic or about to become diabetic, displayed any tendency to increase the blood sugar in recipient ADHA rats.

There is some reason to associate the pancreas with the high insulin requirement of dogs with metahypophyseal-[5] or alloxan-[6] diabetes, relative to that of depancreatized dogs, and moreover the pancreatic islets (α-cells ?) are known to contain a substance antagonistic in some respects to insulin[7]. It was thus of particular interest to test portal vein blood, as well as peripheral blood, from animals treated with growth hormone, for hyperglycæmic activity in ADHA rats.

Methods. ADHA male rats weighing about 220 gm. were deprived of food for 1½ hr., by which time their blood-sugar level was about 100 mgm./100 ml. They were lightly anæsthetized (pentothal) and blood withdrawn from the tail vein for blood-sugar estimation. The sample of blood (1 ml.) from the donor animal (rat or cat) was then injected intravenously into the femoral vein of an ADHA rat, and further blood samples taken from the rat for blood-sugar estimation at 10, 20 and 30 min. after the injection. Blood sugar was estimated on heparinized blood samples by the Harding modification of the Shaffer–Hartman method. In certain experiments glycogen was determined, by the Good–Kramer–Somogyi method, on biopsy samples taken successively from one lobe of the liver with a cutting cautery.

The growth hormone was derived from ox anterior pituitary glands by either of two purification procedures[8].

In the preliminary experiments, in which ADHA donor rats were used, these animals were given 1 mgm. of growth hormone subcutaneously 24 hr. before the blood sample was taken, and a further 0·5 mgm. 1 hr. before sampling. Heparinized blood samples, obtained from the portal vein or from the femoral vein under light pentothal anæsthesia, were injected intravenously into recipient ADHA rats. Some ADHA rats received an intravenous injection of 0·5 mgm. of growth hormone in place of a blood sample.

The cats used were intact male animals, and were given daily subcutaneous injections of purified growth hormone of which, in a typical experiment, a daily dose of 10 mgm. induced a substantial glycosuria (10–20 gm./day) after five days of treatment. Where a 'prediabetic state' of the cats was investigated, only two injections of growth hormone were given.

In cat No. 237, diabetes had been induced by treatment with growth hormone in an initial test, but later this animal had become insensitive to the diabetogenic action of small doses of growth hormone, and was regarded as 'refractory'. Two injections of growth hormone were given before the blood sample

Table 1. Influence of the injection of blood from ADHA rats treated with growth hormone on the blood sugar of recipient ADHA rats (P vein = portal vein; F vein = femoral vein; significance of observation = probability (%) that the difference between the blood-sugar data for control and experimental rats is due to chance)

was taken. No injections were given to cat No. 203 with metahypophyseal diabetes.

Eighty minutes after the last growth-hormone injection (with the exception of cat 238 for which the period was 24 hr.), and 3 hr. after withdrawal of food, the cats were anæsthetized under pentothal. Blood was then withdrawn either from the pancreatico-duodenal vein or from the femoral vein, and administered intravenously to the recipient ADHA rats.

In experiments with control cats, two of which had been treated with an inactivated growth-hormone preparation, five pairs of recipient ADHA rats receiving portal blood yielded data for 10- and 20-min. samples which, on statistical analysis, established that there was no significant variation from one cat to another. This being so, the blood-sugar values in the recipient rats treated with blood from control donor cats were averaged, and the results expressed as the mean value together with the standard deviation for the individual observations. These control values formed the basis on which the significance of the results with treated cats was determined.

Results:

Donor ADHA rats. The results with donor ADHA rats are summarized in Table 1, from which it is clear that a transient but significant rise in the blood-sugar level of recipient rats was produced by the administration of portal blood from animals treated with growth hormone, but not with peripheral blood from such rats, nor with portal blood from rats treated with saline. It is also of interest that when the recipient ADHA rats received injections of growth hormone instead of blood from ADHA rats treated with growth hormone (Table 2), there was no immediate effect on the blood sugar level, although a delayed transient rise was observed in some of the animals. The hyperglycæmic action of blood from donor rats treated with growth hormone was associated with a depletion of liver glycogen in the recipient rats (Table 3).

Table 3. Influence of the injection of blood from ADHA rats treated with growth hormone on the liver glycogen of recipient ADHA rats. (Blood from portal vein. Significance of observation = probability (%) that the difference between the liver glycogen data for control and experimental rats is due to chance)

Donor ADHA rats		Recipient ADHA rats

* With standard deviation of the observations.

Donor cats. Pancreatico-duodenal blood samples from intact cats in which growth-hormone diabetes had been induced, produced in recipient ADHA rats (Table 4) an abrupt rise in the blood-sugar level, although no rise was induced when blood from the femoral vein of donor cats was used. Indeed, in the experiments with diabetic cats 230 and 234, in which the rise of blood sugar in the recipient rats treated with portal blood was somewhat smaller than that for the other diabetic animals, the peripheral blood caused a fall of blood-sugar level in the recipient rats which may well have indicated the presence of insulin in the peripheral blood of the donor cats. Somewhat similar findings were obtained with blood

Table 4. Influence of the injection of blood from cats treated with growth hormone on the blood sugar of ADHA rats.

from 'pre-diabetic' cats. The blood-sugar level of recipient rats was not significantly influenced by pancreatico-duodenal blood from the refractory cat, nor by peripheral blood from the cat with metahypophyseal diabetes.

Discussion. The results indicate that portal blood but not peripheral blood of animals made diabetic by growth hormone exerts a hyperglycæmic effect on recipient ADHA rats. Peripheral blood, on the other hand, sometimes causes a significant fall in the blood-sugar level of recipient ADHA rats such as might indicate the presence of insulin. These results are consistent with the view that growth-hormone treatment causes the liberation of the hyperglycæmic substance from the pancreatic islets, and that this substance, in contrast with insulin, does not reach the peripheral veins in appreciable amounts.

It must be admitted that other interpretations of these results are not ruled out by the present experiments. Since, however, pancreatico-duodenal or portal vein blood from suitable animals treated with growth hormone exerts a hyperglycæmic action in ADHA rats, the simplest hypothesis, namely, that this effect is due to the presence in portal blood of the hyperglycæmic substance from pancreatic islets, may be accepted until evidence disproving it is obtained.

We do not wish to discuss here the possibility that the influence of growth hormone on carbohydrate metabolism is mediated in part or wholly by secretion of the pancreatic hyperglycæmic factor. We do wish to point out, however, that since the factor is not confined to the pancreatic islets[7], experiments demonstrating an action of growth hormone on the carbohydrate metabolism of completely depancreatized animals[9] do not finally exclude this possibility.

Summary. Pituitary growth hormone was given to alloxan-diabetic-hypophysectomized-adrenalectomized rats, or to intact cats under conditions such that diabetes was induced. Portal blood from these animals was consistently found to exert a hyperglycæmic action when administered to recipient alloxan-diabetic-hypophysectomized-adrenalectomized rats. Such a hyperglycæmic effect was not found when growth hormone was administered directly to the recipient rats. These observations are consistent with the view that under the influence of growth hormone the pancreatic islets liberate their contained hyperglycæmic substance into the portal blood.

We are grateful for the technical assistance we received, particularly from Mr. M. Snowdon, and for financial assistance given by the Medical Research Council to one of us (F. G. Y.) and by Boots Pure Drug Co., Ltd., to another (J. B.).

LONGEVITY OF *NELUMBO* FRUITS

CONSIDERABLE interest was aroused in Great Britain in 1933 by the flowering at the Royal Botanic Gardens, Kew, of plants of the sacred lotus (*Nelumbo nucifera* Gaertner, syn. *Nelumbium speciosum* Willd.) raised from fruits taken there by a Japanese botanist, Ichiro Ohga, who had found them in the peat of a long-dried-up Manchurian lake (*Bot. Mag. Tokyo*, 37, 87; 1923).

A like interest has been aroused this year in the United States by the germination at Washington in March 1951 of *Nelumbo* fruits having the same origin. These fruits came from a peat layer overlaid by several feet of loess on which trees grew; hence Ohga concluded that they must be at least 300–400 years old. Nelumbo fruits are nut-like and commonly regarded as seeds, the apparent fruit being a large obconical receptacle; they have a very hard coat impervious to air and water, and will not germinate until this coat has been broken or softened, for example, by filing or by the use of concentrated sulphuric acid. Fruits known to be 150 years old were germinated by Robert Brown; others known to be fifty-six years old were germinated by Becquerel (see *Kew Bulletin*, 263; 1933). An interesting paper on "How old are the Manchurian Lotus Seeds?" by Prof. Ralph W. Chaney, Department of Paleontology, University of California, indicates that these Manchurian fruits may have retained their vitality over a period much exceeding four hundred years, possibly for thousands of years.

The sequence of events, as outlined by Chaney in *The Garden Journal of the New York Botanical Garden*, 1, No. 5, 137 (September 1951) and by Ohga, seems to have been as follows. On the floor of a lake, about a mile across, in the Pulantien Basin of southern Manchuria, there accumulated a thick layer of plant fragments, among them the durable fruits of the lotus, a species which grows in shallow water. This process may have taken several centuries. Later the lake drained, and dust from the Gobi desert covered the peat with several feet of loess. The Japanese geologist Endo believes this loess deposit to be of Pleistocene age and the peat layer and its fruits to be 50,000 years old; if so, these fruits may have begun their long sleep at a time when Peking man (*Pithecanthropus pekinensis*) roamed eastern Asia.

To botanists accustomed to the short period during which most seeds and fruits retain their vitality, Ohga's estimate of a longevity of four hundred years was startling; Endo's estimate of 50,000 years accordingly seems fantastic, although a form of packing which protected the embryo and its food-reserves against molecular change so effectively for four hundred years might well protect them indefinitely. There can be no doubt that these Manchurian lotus fruits are very old. The species nowadays does not grow wild within a thousand miles of the Pulantien lake, and these Pulantien fruits differ in size and shape from those of the modern Indian form of the species with which they have been compared. A preliminary investigation by Dr. W. F. Libby, University of Chicago, of the residual carbon-14 isotope of a few fruits available in the United States puts their age at 1,040 years (± 210) according to a note in *Science*, 114, 296 (September 1951). Further investigation is planned.

The retention of viability by *Nelumbo* fruits for a thousand years or so is in its way as great a botanical sensation as the discovery of *Metasequoia glyptostroboides* a few years ago.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Is there an Æther ?

In the last century, the idea of a universal and all-pervading æther was popular as a foundation on which to build the theory of electromagnetic phenomena. The situation was profoundly influenced in 1905 by Einstein's discovery of the principle of relativity, leading to the requirement of a four-dimensional formulation of all natural laws. It was soon found that the existence of an æther could not be fitted in with relativity, and since relativity was well established, the æther was abandoned.

Physical knowledge has advanced very much since 1905, notably by the arrival of quantum mechanics, and the situation has again changed. If one re-examines the question in the light of present-day knowledge, one finds that the æther is no longer ruled out by relativity, and good reasons can now be advanced for postulating an æther.

Let us consider in its simplest form the old argument for showing that the existence of an æther is incompatible with relativity. Take a region of space-time which is a *perfect vacuum*, that is, there is no matter in it and also no fields. According to the principle of relativity, this region must be isotropic in the Lorentz sense—all directions within the light-cone must be equivalent to one another. According to the æther hypothesis, at each point in the region there must be an æther, moving with some velocity, presumably less than the velocity of light. This velocity provides a preferred direction within the light-cone in space-time, which direction should show itself up in suitable experiments. Thus we get a contradiction with the relativistic requirement that all directions within the light-cone are equivalent.

This argument is unassailable from the 1905 point of view, but at the present time it needs modification, because we have to apply quantum mechanics to the æther. The velocity of the æther, like other physical variables, is subject to uncertainty relations. For a particular physical state the velocity of the æther at a certain point of space-time will not usually be a well-defined quantity, but will be distributed over various possible values according to a probability law obtained by taking the square of the modulus of a wave function. We may set up a wave function which makes all values for the velocity of the æther equally probable. Such a wave function may well represent the perfect vacuum state in accordance with the principle of relativity.

One gets an analogous problem by considering the hydrogen atom with neglect of the spins of the electron and proton. From the classical picture it would seem to be impossible for this atom to be in a state of spherical symmetry. We know experimentally that the hydrogen atom can be in a state of spherical symmetry—any spectroscopic S-state is such a state—and the quantum theory provides an explanation by allowing spherically symmetrical wave functions, each of which makes all directions for the line joining electron to proton equally probable.

We thus see that the passage from the classical theory to the quantum theory makes drastic alterations in our ideas of symmetry. A thing which cannot be symmetrical in the classical model may very well be symmetrical after quantization. This provides a means of reconciling the disturbance of Lorentz symmetry in space-time produced by the existence of an æther with the principle of relativity.

There is one respect in which the analogy of the hydrogen atom is imperfect. A state of spherical symmetry of the hydrogen atom is quite a proper state—the wave function representing it can be normalized. This is not so for the state of Lorentz symmetry of the æther.

Let us assume the four components v_μ of the velocity of the æther at any point of space-time commute with one another. Then we can set up a representation with the wave functions involving the v's. The four v's can be pictured as defining a point on a three-dimensional hyperboloid in a four-dimensional space, with the equation:

$$v_0^2 - v_1^2 - v_2^2 - v_3^2 = 1 \qquad v_0 > 0. \quad (1)$$

A wave-function which represents a state for which all æther velocities are equally probable must be independent of the v's, so it is a constant over the hyperboloid (1). If we form the square of the modulus of this wave function and integrate over the three-dimensional surface (1) in a Lorentz-invariant manner, which means attaching equal weights to elements of the surface which can be transformed into one another by a Lorentz transformation, the result will be infinite. Thus this wave function cannot be normalized.

The states corresponding to wave functions that can be normalized are the only states that can be attained in practice. A state corresponding to a wave function which cannot be normalized should be looked upon as a theoretical idealization, which can never be actually realized, although one can approach indefinitely close to it. Such idealized states are very useful in quantum theory, and we could not do without them. For example, any state for which there is a particle with a specified momentum is of this kind—the wave function cannot be normalized because from the uncertainty principle the particle would have to be distributed over the whole universe—and such states are needed in collision problems.

We can now see that we may very well have an æther, subject to quantum mechanics and conforming to relativity, provided we are willing to consider the perfect vacuum as an idealized state, not attainable in practice. From the experimental point of view, there does not seem to be any objection to this. We must make some profound alterations in our theoretical ideas of the vacuum. It is no longer a trivial state, but needs elaborate mathematics for its description.

I have recently[1] put forward a new theory of electrodynamics in which the potentials A_μ are restricted by:

$$A_\mu A_\mu = k^2,$$

where k is a universal constant. From the continuity of A_0 we see that it must always have the same sign and we may take it positive. We can then put

$$k^{-1} A_\mu = v_\mu \quad (2)$$

and get v's satisfying (1). These v's define a velocity. Its physical significance in the theory is that if there is any electric charge it must flow with this velocity, and in regions where there is no charge it is the velocity with which a small charge would have to flow if it were introduced.

We have now the velocity (2) at all points of space-time, playing a fundamental part in electrodynamics. It is natural to regard it as the velocity of some real physical thing. Thus with the new theory of electrodynamics we are rather forced to have an æther.

The Proportional Counter in X-Ray Diffraction Work

Recent work, for example, that by Curran *et al.*[1], has shown how the proportional counter can be made a reliable tool for measuring the energies of soft radiations. Used as a detector for measuring the intensities of diffracted X-rays, it possesses many advantages over the Geiger counter. With the proportional counter, counting losses are entirely negligible for all X-ray intensities likely to be realized with conventional X-ray generators and diffraction techniques. The possibility of discriminating against unwanted radiations of wave-lengths other than that of the characteristic radiation used for diffraction purposes enables diffraction records of greatly improved quality to be obtained, especially when the specimen gives rise to appreciable fluorescent radiation. Particularly valuable is the ability to cut out radiation the wave-length of which is a submultiple of that of the characteristic radiation. The life of the proportional counter is practically infinite, and so it is much more economical than the organic-vapour-quenched Geiger counters commonly employed as X-ray detectors.

A cylindrical brass-bodied proportional counter has been used mounted with its axis at right angles to the diffracted X-ray beam, which enters by a thin beryllium window. The counter was filled to atmospheric pressure with argon plus ethylene. Amplified counter pulses pass through a variable-width single-channel pulse analyser the output of which feeds a scaling unit and/or rate-meter with graphical recorder.

Fig. 1 shows that radiation of wave-length λ = 1·54 A. and energy 8·05 keV. (copper *Kα*) is completely separated from the harmonic wave-length of λ = 0·77 A. and energy 16·1 keV. Curve (*a*) was obtained with characteristic radiation reflected by plane 200 of a lithium fluoride plate set at the appropriate glancing angle, the X-ray tube being run at 30 kV. Curve (*b*) shows radiation of wave-length λ = 0·77 A. obtained by reducing the glancing angle, increasing the X-ray tube voltage to 50 kV., and doubling the X-ray tube current. On curve (*a*) a low peak at 16 keV. is due to the presence of radiation of wave-length λ = 0·77 A. from the second-order reflexion, 400. The harmonic is thus present in noticeable amount even at the low X-ray tube voltage of 30 kV. The small peaks on the low-energy side of both the 8 keV. and 16 keV. peaks are due to a small fraction of energy being lost as argon fluorescent *K* radiation which was not absorbed in the counter gas.

Figs. 2*a* and *b* show counter spectrometer records of part of the diffraction spectrum of powdered chrome alum taken by Geiger counter in Fig. 2*a* and by proportional counter in Fig. 2*b*. Copper *Kα* radiation was used, and in each case a nickel β filter

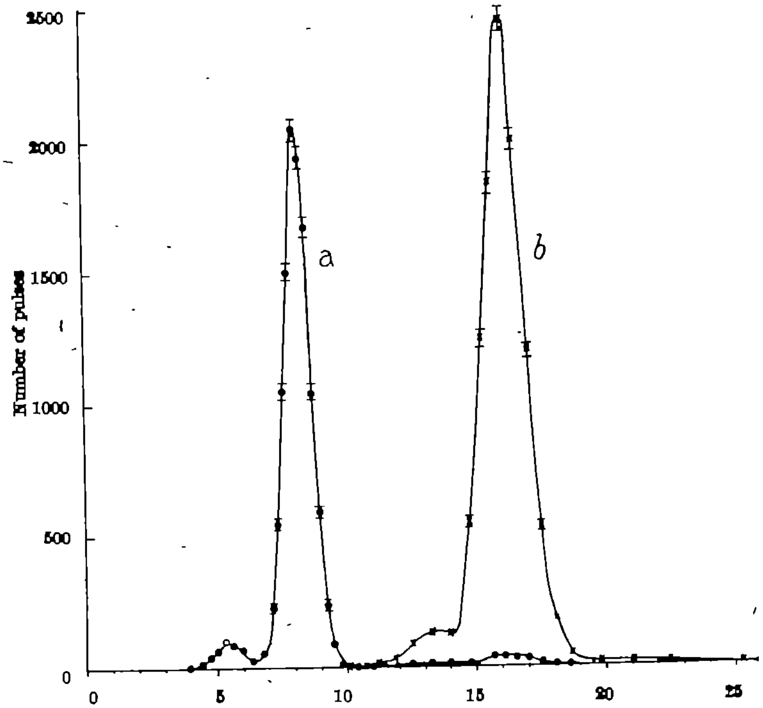

Fig. 1

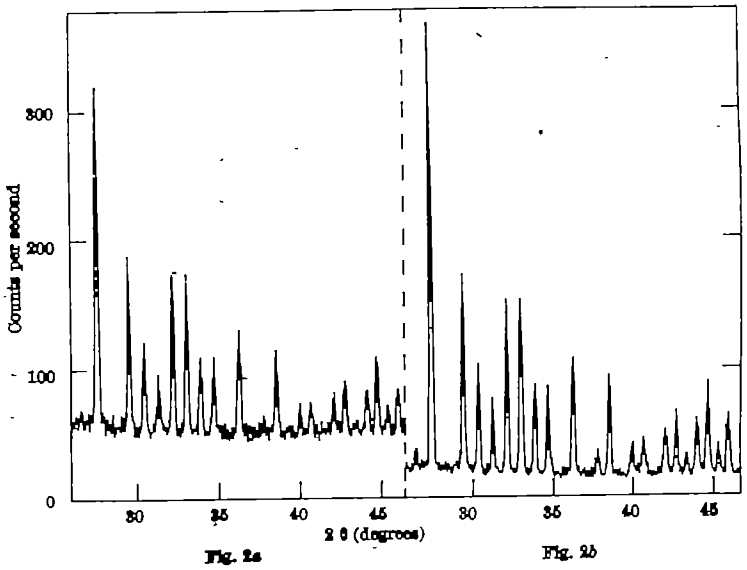

Fig. 2a Fig. 2b

was placed in front of the counter window. The two runs were made under identical conditions, only the counters being changed. It will be seen that the background in the proportional counter record is only about one quarter of that in the Geiger counter record. Several weak lines that can be barely distinguished above the statistical fluctuations of the high background in the Geiger counter record stand out clearly in the proportional counter record and allow reasonable estimates to be made of their intensities. Comparison of peak heights in the two curves shows that the proportional counter has a higher sensitivity for copper *Kα* radiation than the Geiger counter used, which was the best commercially available type. The natural background-rate of the proportional counter falling in the channel used for copper *Kα* radiation measurements was 15 counts per minute, only a quarter of that of the Geiger counter.

This work was supported by a grant from the British Electrical and Allied Industries Research Association.

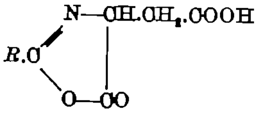
Racemization of N-Acylaspartic Acids

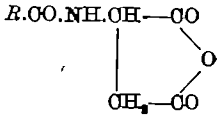
An exception to the general applicability of the method devised by du Vigneaud and Meyer[1] for the racemization of N-acyl-α-amino-acids has been discovered in the course of an attempt to racemize N-acetyl- and N-benzoyl-L-aspartic acids. The method of du Vigneaud and Meyer depends for its success upon the intermediate formation of a readily racemizable oxazolone when an aqueous solution of the sodium salt of such an acid is stirred with acetic anhydride. This treatment, which leads to the complete racemization of the N-acetyl derivatives of optically active methionine, cystine, arginine, tyrosine, phenylalanine, tryptophane and glutamic acid[1,2], achieves, however, only 13 per cent and 24 per cent racemization when applied to N-acetyl- and N-benzoyl-L-aspartic acids respectively.

The N-acylaspartic acids are unique in that they can, theoretically, become dehydrated in three alternative ways to give oxazolones (I), true anhydrides (II), and dihydro-6-keto-1 : 3-oxazines (III) respectively. The latter type of compound has received but little study; Baker and Ollis[3] have prepared 5 : 6-dihydro-6-keto-4 : 4-dimethyl-2-phenyl-1 : 3-oxazine from β-benzamido*iso*valeric acid, and pointed out that this type of compound may play a part in the chemistry of N-acylaspartic acids. Since the preferential formation of the anhydride or the dihydro-1 : 3-oxazine would account for the failure to racemize, the structures of the crystalline products obtained from these acids by the action of acetic anhydride have now been examined.

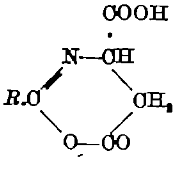
In this connexion it is of interest that Harington and Overhoff[4] obtained two dehydration products, melting points 145° and 175° respectively, from N-acetyl-L-aspartic acid and acetic anhydride. They ascribe to the former the oxazolone structure, on the grounds that it gives 2-methyl-5-oxazolone-4-acetyl chloride when treated with phosphorus pentachloride, while the anhydride structure is ascribed to the isomer of higher melting point without evidence. It has now been established that they both possess the anhydride structure, and that they are the racemic and optically active forms respectively. The isomer of lower melting point is invariably formed from N-acetyl-DL-aspartic acid; but either form may be obtained from the optically active acid. To obtain consistently the optically active anhydride, the N-acetyl-L-aspartic acid, which could not be obtained crystalline, must be quite free from sodium acetate, which is present as a contaminant when an aqueous alkaline acetylation of L-aspartic acid has been carried out.



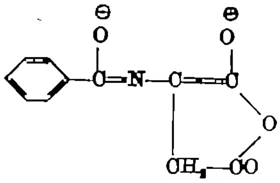
I



II



III



IV

The anhydride structure of these compounds is indicated by their total lack of reactivity towards diazomethane, by the formation of an α-amide with ammonia (thus eliminating structure III), and by the failure of the optically active anhydride to be racemized upon hydrolysis in aqueous sodium acetate (thus eliminating structure I). The structure is confirmed by the formation with aniline of two anilides, melting points 199° and 176–179° (decomp.) respectively. Similar considerations lead to the allocation of the anhydride structure to the anhydro N-benzoyl-L-aspartic acid.

The demonstration of the structures of these crystalline products does not, of course, rule out the presence of other anhydro-products at equilibrium in solution. The partial racemization produced by applying the method of du Vigneaud and Meyer may be due to some oxazolone formation, while the more complete racemization, produced when N-acetyl-L-aspartic acid is heated with acetic anhydride containing a little sodium acetate, may be due to the same cause. It has been established, however, that racemization can occur in such a medium when oxazolone formation is impossible, for example, the racemization of N-acetyl-L-proline[5]. Such racemization probably occurs as a result of the enolization of the anhydride, and new support for this mechanism is found in the observation that the water-insoluble N-benzoyl-L-aspartic anhydride dissolves readily in dilute sodium hydroxide to give a faintly yellow solution, which has an intense blue fluorescence in ultraviolet light. Both colour and fluorescence fade during the course of an hour as hydrolysis to the sodium salt of the acid occurs, and the product is completely racemized. The colour, fluorescence and racemization seem to be best explained by postulating the formation of the ion (IV).

As anticipated, N-benzoyl-L-asparagine is almost completely racemized (95 per cent) when its sodium salt is stirred with aqueous acetic anhydride.

A fuller account of these investigations will be published elsewhere.

A New View of the Arylhydroxylamine Rearrangement

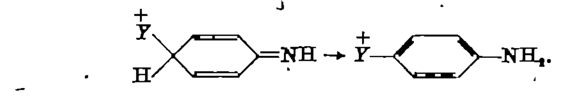
IT is a commonplace that those acid-catalysed aromatic rearrangements, which conform to the general pattern,

$$C_6H_5.NRX \xrightarrow{\text{acid}} (o\text{- or } p\text{-})\ X\cdot C_6H_4.NHR,$$

$$X = Cl, Br, I, NO_2, NO, SO_3H, OH, NHAr, N_2Ar, Alk,$$

notwithstanding that they are formally so similar, do not all proceed by the same mechanism: some involve intermolecular processes and some intramolecular. But they are usually all held to have at least this in common, namely, that X migrates as an electrophilic fragment: whatever adventures it may go through while in transit, it separates from nitrogen without the electrons by which it was bound thereto, and it unites with aromatic carbon by means of electrons which the latter has to supply. Such rearrangements may be called 'electrophilic rearrangements'.

This communication presents the view that there are actually at least two classes of rearrangements among the examples formulated above; that most of them are, indeed, electrophilic rearrangements; but that the arylhydroxylamine rearrangement, in particular, exemplifies the opposite process, a 'nucleophilic rearrangement': the OH group separates from nitrogen with the electrons with which it was bound; and a nucleophilic OH fragment uses its own unshared electrons for the purpose of combining with a carbon kernel. With the customary ellipsis of allowing single valency structures to represent mesomeric systems, the proposed mechanism may be formulated for a *para*-rearrangement as follows:



In the strictly isomeric change, Y: would be a water molecule; but taking closely related non-isomeric substitutions into account, Y: could be any sufficiently accessible and reactive nucleophilic molecule or anion. The mechanism is here formulated in an S_N1' manner, in accordance with the present evidence; but an S_N2' form of it may also exist, in which the first two stages, as written, would become telescoped into a single stage.

This is not the picture hitherto presented of the arylhydroxylamine rearrangement: reference may be made to a recent discussion by Dewar[1]. Because the transference of hydroxyl from an arylhydroxylamine to a foreign amine or phenol has not been achieved[2], and because hydrogen peroxide is not known to be produced during rearrangement in water, Dewar concludes that the rearrangement is electrophilic and intramolecular, adding the rider that it illustrates his π-bond theory (in which X^+, though bound, travels freely over the π-shell until it 'holes out' at an *ortho*- or *para*-position).

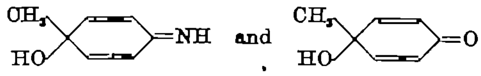
Our case for the view that the rearrangement is, on the contrary, nucleophilic and intermolecular, is based on the study of its kinetics and products. The significant work on products is in the literature already, and is due chiefly to Bamberger[3]. When phenylhydroxylamine was rearranged by means of dilute aqueous sulphuric acid, *p*-aminophenol was the main product. However, when ethyl alcohol was used for diluting the acid, *o*- and *p*-phenetidines, and with methyl alcohol, anisidines, were formed; and when the acid employed was hydrochloric acid, *o*- and *p*-chloroanilines were produced. If phenol was added, the product contained $(p)OH.C_6H_4.C_6H_4.NH_2(p)$ and some $C_6H_5.NH.C_6H_4.OH(p)$, and if aniline was introduced, some $C_6H_4.NH.C_6H_4.NH_2(p)$. Formed *p*-aminophenol was in some cases accompanied by the ether, $(p)NH_2.C_6H_4.O.C_6H_4.NH_2(p)$. The fact that so many fragments can appear in place of OH in the arylhydroxylamine–aminophenol conversion strongly suggests that the latter is not an intramolecular rearrangement. Further, since all the fragments come from nucleophiles:

$$Y = H_2O,\ EtOH,\ MeOH,\ Cl^-,\ PhOH,\ PhNH_2,\ NH_2.C_6H_4.OH,$$

one is led to assume an active electrophilic intermediate.

Bamberger found that the products obtained from an arylhydroxylamine were essentially identical with those produced by nitrogen loss from the corresponding aryl azide in similar conditions. He assumed a common univalent-nitrogen intermediate, ArN, which, when supplied with the extra proton shown by the kinetics to be involved (see below), becomes identical with the carbonium ionic intermediate written above.

By rearranging *p*-tolylhydroxylamine in aqueous acid at low temperatures, Bamberger demonstrated the formation of the iminoquinol and quinol,



along with products derived from them. This is where the previously written sequence of reactions would stop, when the final prototropic change is blocked by methyl substitution.

Bamberger found aniline and azoxybenzene among the products obtained from phenylhydroxylamine. But these substances probably arose from the irrelevant oxidation-reduction of phenylhydroxylamine. Our experiments indicate this to be a chain-reaction, avoidable, but easily started by short exposures to atmospheric oxygen. However, we find that the acid-catalysed rearrangements of phenylhydroxylamine are quite separate from these reactions, and are not dependent on the presence of oxidants.

Our kinetic study shows further that the rearrangements depend on the cation of phenylhydroxylamine, $PhNH_2OH^+$ (to write it in its more stable, rather than its more reactive, form). One consequence of this is that, while at low acidities the rate is proportional to the acidity, it ceases to increase proportionally to the acid when enough acid has been introduced to ionize nearly the whole of the base. No evidence has yet been found that chloride ion becomes involved in the rate-determining process, even when chlorine appears in the product. No sign has been discovered of quadratic dependence on acid, as in the benzidine change.

We think it would be very difficult to accommodate all these facts on any other view of the reaction than that advanced. But the matter is still being tested. As to products, Dr. C. A. Bunton is checking oxygen identities among factor, product and solvent, by the use of heavy-oxygen water; and as to kinetics, evidence of an S_N2' form of the reaction is being sought.

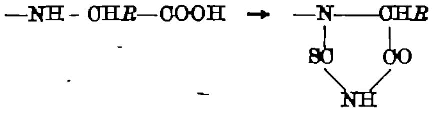
Identification of the Free Carboxyl Groups in Peptides

THE Schlack and Kumpf procedure[1] for identifying the amino-acids which provide terminal carboxyl groups in peptides has been made the basis of a micro method which works well with simple peptides and may be of use in studying the free α-carboxyl groups in proteins. In the case of glycylleucine and glycylvaline, the method has been used successfully, although preliminary experiments with insulin and wool keratin have indicated that some modification of the procedure may be necessary before it can be used with proteins.

Dry ammonium thiocyanate (0·1 gm.) and acetic anhydride containing 10 per cent acetic acid (1·0 ml.) are heated with the benzoylated dipeptide (0·1 gm.) for 30 min. on a boiling water-bath. After cooling the orange solution, 50 ml. of water is added, the mixture left overnight, and the light brown precipitate filtered off. It is then washed well with water and dried; yield 0·1 gm.



The thiohydantoin derivative of the benzoylated dipeptide (20 mgm.) is refluxed with 20 per cent hydrochloric acid (10 ml.) for 8 hr. and the hydrolysate extracted twice with nitromethane. After washing with water, the extract is taken to dryness *in vacuo* and hydrolysed in a sealed tube with 10 ml. of 0·25 *N* barium hydroxide for 48 hr. at 140° C.[2]. The barium hydroxide is removed as carbonate and the hydrolysate evaporated down and examined for amino-acids by paper chromatography. Ninhydrin development of the chromatogram shows a clear spot corresponding to the acid carrying the free carboxyl group. No other spot could be observed.

Influence of Salt on the Size and Shape of a Protein – Detergent Complex

STUDIES of the interactions between detergent and protein solutions by a wide variety of techniques have provided useful information on the types of binding involved in these systems[1] and on the denaturation and re-orientation of protein molecules[2]. In particular, the system bovine serum albumin – sodium dodecyl sulphate has been extensively investigated by electrophoresis, sedimentation and viscosity methods by Putnam and co-workers[3], and the heats of interaction for this system have recently been measured in this Laboratory by a direct calorimetric method[4]. The present communication deals with the effect of salt on the turbidity of bovine serum albumin – sodium dodecyl sulphate solutions.

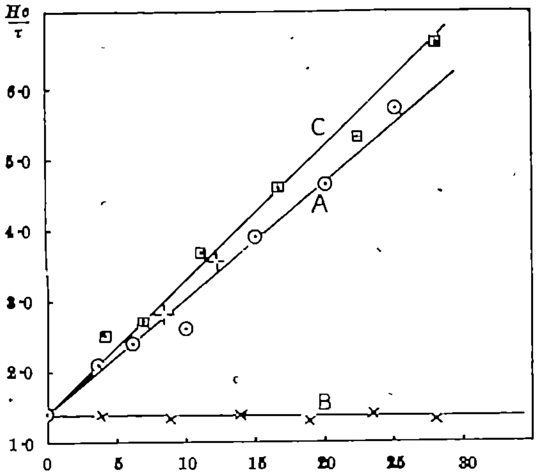
The light-scattering apparatus used was similar in principle to that already described[5], with the improvement that variations in the intensity of the incident light were corrected by reflecting a constant fraction of the latter on to a second photomultiplier tube. Moreover, since intensities of the scattered light were measured at 50° and 130° as well as at 90° to the incident beam, a large circular glass water-bath was placed around the optical cell containing the scattering solution in order to minimize reflexions and water–air refractive index corrections. The apparatus was calibrated by measurement of the turbidity of solutions of bovine serum albumin, a molecular weight of 70,000 being assumed for this protein. Since the protein solutions showed no dissymmetry of scattering, the turbidity (τ) could be calculated from the equation[6]:

$$1/M = \frac{32\pi^3 n_0^2 (dn/dc)^2}{3N_0 \lambda_0^4} \cdot \frac{c}{\tau} + 2\,Bc = \frac{Hc}{\tau} + 2\,Bc\,;$$

where M is the molecular weight of the protein, c its concentration in gm./c.c., dn/dc its refractive increment in solvent of refractive index n_0, N_0 is Avogadro's number, B and H are constants.

The refractive index increments were determined with a Rayleigh–Haber interferometer (Hilger). Solutions were optically clarified by gravity filtration through sintered glass, Grade 4 (clarification was not complete if suction were used), or, in the case of solutions containing sodium hydroxide, by centrifugation.

Curve *A* in the accompanying graph shows the value Hc/τ as a function of the detergent/protein ratio for the system sodium dodecyl sulphate – bovine serum albumin in salt-free solutions. The concentration of protein was maintained constant throughout at 1 per cent (w/v). Since the addition of detergent has little effect on the refractive increment, dn/dc, of the protein, the linear increase in Hc/τ with detergent/protein ratio is due almost entirely to a decrease in turbidity. Curve *B* shows that this



Curves *A* and *B*, detergent/protein ratio (moles); curve *C*, sodium hydroxide/protein ratio (moles)

Hc/τ as a function of detergent (or sodium hydroxide)/protein ratio. □, Sodium hydroxide – 1 per cent bovine serum albumen, + and ○, sodium dodecyl sulphate – bovine serum albumen (two samples), salt-free; ×, sodium dodecyl sulphate – bovine serum albumen in 0·01 *N* sodium chloride

diminution in turbidity is eliminated by the presence of sodium chloride at a concentration of 0·05 molar. Curve *C* shows that a diminution in turbidity comparable with that in curve *A* may be produced by titrating the protein with sodium hydroxide. The protein concentration was maintained at 1 per cent (w/v) during this titration.

The diminution in turbidity shown in curve *A* appears to be due to combination of the serum albumin with detergent anions, resulting in the protein acquiring a net negative charge. On titration with alkali the protein will also acquire a net negative charge. Doty and Steiner[7] have predicted on theoretical grounds that the turbidity of salt-free solutions of large molecules is reduced if the molecules are charged. As expected, the effect disappears in the presence of salt.

In all the solutions for which results are shown in the graph, the dissymmetry ratio of scattering (I_{45}/I_{135}) was approximately equal to unity. If, however, solutions were prepared in which the detergent/protein ratio was 140 moles, dissymmetry ratios of 1·5–1·6 were observed. This suggests an unrolling of the protein molecule at high detergent/protein ratios. The addition of solid sodium chloride to these solutions resulted in an increased turbidity (cf. curve *B*) and in a fall in the dissymmetry ratio to less than 1·10, indicating that the protein-detergent complex takes on a more symmetrical configuration in the presence of salt. Because of this dissymmetry effect at high detergent/protein ratios, it was found that the method of mixing detergent and protein solutions at lower ratios is important. If the protein solution is slowly added to the detergent solution so that initially there is a high detergent/protein ratio, dissymmetry ratios of approximately 1·5 are observed, whereas if the same solutions are mixed in the reverse order, dissymmetry ratios of approximately unity are found.

Neurath and Putnam[8] have measured the intrinsic viscosities of protein–detergent mixtures, and for this system have found evidence for denaturation of the protein, as a complex is formed at a detergent/protein ratio of about 100 moles. However, these experiments were carried out in buffered salt solutions. In solutions containing salt, no dissymmetry of light scattering is found, suggesting that in salt-free solutions an even greater uncoiling of the protein molecules occurs than that found by Neurath and Putnam. It has been observed qualitatively that the viscosities of salt-free solutions containing a high detergent/protein ratio are greater than for those containing salt. Quantitative measurements of the viscosities of salt-free solutions are now in progress.

Prediction of Internuclear Distances of Di-atoms

SEVENTEEN years ago[1], on the basis of my proposed modification of the Morse rule connecting fundamental vibration frequency and internuclear distance of di-atoms, I ventured to predict internuclear distances for certain cases which had not then been determined experimentally. The accompanying table compares the values predicted for di-atoms of the *KKpp* sub-period with experimental results given in a new table due to Herzberg[2]. In some cases, the fundamental frequencies on which the calculations depend have been shifted by a few wave-numbers. In spite of these small corrections, it is judged sufficient to make direct comparison between the two sets of numbers without further calculation.

Di-atom	Electronic state	r_e (A.), predicted	r_e (A.), exp.	Error
CO	$a\ {}^3\Pi_r$ $a'\ {}^3\Sigma+$ $X\ {}^1\Sigma+$	1·202 1·367 1·117	1·209 1·359 1·128	− 0·007 + 0·008 − 0·011
NN	$a\ {}^1\Pi_g$ $C\ {}^3\Pi_u$	1·213 1·139	1·213 1·148	0·000 − 0·009
NO	$D\ {}^2\Sigma+$	1·070	(1·065)	+ 0·005
OO	$b\ {}^1\Sigma_g+$ $a\ {}^1\Delta_g$	1·238 1·218	1·227 1·216	+ 0·011 + 0·002
			Mean error	0·007

Results predicted in 1939[3] for singlet and triplet states of HH, HD and DD appear to have about the same errors, and many other cases may be cited. Improved methods have been more recently devised[4] interrelating bond constant and internuclear distance.

My classification[5] of di-atoms into groups, sub-groups, periods and sub-periods, and the introduction of period constants and group numbers into the Morse rule, upon which the above results depend, appears to be vindicated as a working basis. Careful comparison with the errors in calculated numbers derived by formulæ due to other authors seems to weigh in favour of my system. It may be claimed that the original method employed by Mendeljéeff in his atomic periodic table, and successful prediction of physical constants, may be satisfactorily carried over to the spectroscopic data for di-atoms.

A fuller account of this work will appear elsewhere.

Effect of Phosphates and the *p*H on Sugar Absorption

There has been little discussion on the work of Magee and Reid[1] showing that the addition of phosphates at *p*H 7 to the liquid to be absorbed activates intestinal absorption of glucose but not that of xylose[1–3]. Laszt[3] attributes such an effect to the buffer action of the phosphates, as with other buffers at *p*H 7 he obtained analogous increases; between *p*H 4 and 8 he found an optimum of absorption at *p*H 7. Gellhorn and Moldavsky[4], however, arrived at opposite conclusions; in their opinion absorption would be much greater if instead of maintaining the *p*H at 7, it is somewhat displaced towards the acid or alkaline side. Difficulties in the interpretation of other results have induced us to return to these problems.

Absorption was studied in rats of 100–200 gm. by Sols and Ponz's method[7,8]. Three or four successive absorptions were carried out in the same intestinal loop of each animal. The hexoses remained at 5·4 per cent and the pentoses at 4·5 per cent dissolved in water or in phosphate solutions or other buffers. The time for absorption was 15, 20, 30, 45 or 60 min. The *p*H was tested by electrometric and colorimetric methods.

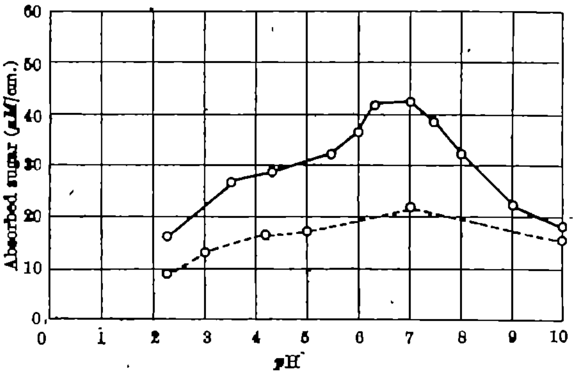

Fig. 1. Influence of *p*H on the absorption of 5·4 per cent D-glucose (———) and 4·5 per cent D-xylose (– – – – – –). Time of absorption, 30 min. for D-glucose and 45 min. for D-xylose. Average values in 41 animals

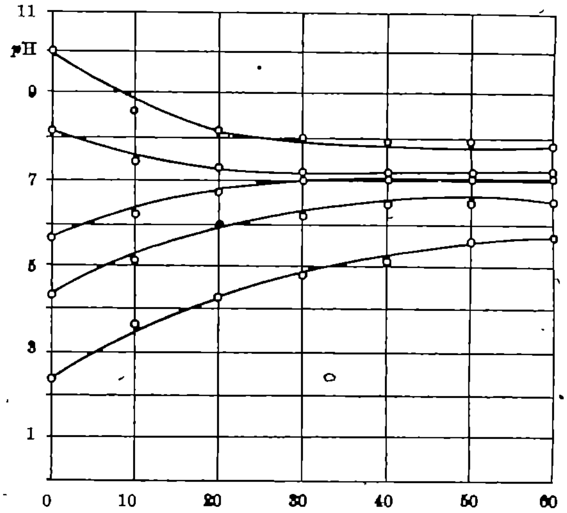

Fig. 2. Neutralization of buffer solutions of different *p*H introduced into the jejunum of rats, as a function of time. Each curve represents the average value obtained in three animals

Experiments on 46 rats showed clearly that the intestinal absorption of glucose was not increased, either by the presence of sodium glycerophosphate (at 2 per cent, neutralized with N/10 hydrochloric acid) or by inorganic phosphates (mixtures of *p*H 7, at 0·2 or 0·02 per cent).

The *p*H (between 2·2 and 10·0) nevertheless influences intestinal absorption. Citric acid–phosphate (McIlvaine, *p*H 2·2–8·0), phosphates (Sörensen, *p*H 5·5–8·0), borax–boric acid (Palitzsch, *p*H 7·0–9·0), and carbonate–bicarbonate (*p*H 10·0) were used. The results were obtained from experiments in thirty rats with D-glucose, eleven with D-xylose, ten with D-arabinose and another ten with L-sorbose. The optimum absorption of D-glucose (selective sugar) and of D-xylose (relatively selective sugar) is found in the interval 6·5–7·5, and it falls remarkably at lower or higher *p*H. Between 6·5 and 7·5, the differences are not statistically significant. At *p*H 3·5 and 9·0, absorption of D-glucose was only 50 per cent. D-Xylose exerts a minor influence (Fig. 1). D-Arabinose and L-sorbose do not seem to be affected by the *p*H. With a strongly acid *p*H, decrease of absorption occurred, and also in a control experiment performed immediately afterwards at *p*H 7; but in all these cases considerable epithelial desquamation presented itself, to which we attributed this effect.

The fact that glucose absorption is not accelerated by the phosphates may be due to the unbuffered D-glucose solutions being conserved in the intestine at *p*H between 6·5 and 7·5 and, therefore, within the optimum zone. The mucosa is, in effect, capable of producing a notable buffer action. We have followed up the *p*H of the intestinal contents during the absorption of D-glucose, starting from buffer solutions at different *p*H. Fig. 2 shows some examples of this buffer action of the jejunum. The more acid or alkaline the solution put into the loop, the greater is the quantity of mucine segregated and found in the intestinal contents. The intestine thus tends to maintain a neutral pH, in which condition the selective absorption of sugars is greatest.

Gene Function in the Homologous and Heterologous Induction of α-Glucosidases in Yeast by α-Glucosides

A variety of freely segregating genes which specifically control the abilities of yeast to ferment α-glucosides has been discovered[1,2]. The three non-allelic genes determining the abilities of the haploid yeasts of the Carbondale breeding stock to grow with attendant visible gas evolution on maltose, α-methyl glucoside and sucrose, respectively, have been designated *MA*/*ma*, *MG*/*mg* and *SU*/*su*. It has been shown that these genes are concerned in the synthesis by the cell of maltase, an α-heteroglucosidase[3] and β-fructofuranosidase, respectively.

Experiments in which the variation of the fermentative scope of cells of genotype *MG MA su*, *mg MA su*, and *MA mg su* was determined in relation to the carbohydrate component of the growth medium of these cells have now permitted a fuller definition of the functions of *MA* and *MG*. Although the strains of these genotypes lack the gene *SU*, that is, they are incapable of growing with attendant visible gas evolution on medium containing sucrose as the sole carbohydrate nutrient, they all proved capable of sucrase synthesis when grown on a suitable carbohydrate. The sucrase activity which could be induced in these strains was frequently held largely in a covert condition by the freshly harvested cells, but was manifested by the same cells after drying. The strains realized only a small or negligible fraction of their glucosidase synthesizing potential when they were grown on glucose. In the strains containing the gene *MA* without *MG*, growth on maltose elicited a homologous response (maltase synthesis) and a heterologous response (synthesis of a sucrase). The growth of these strains on maltose failed to endow them with ability to ferment methyl glucoside at a significant rate. The strains of this genotype were incapable of responding to α-methyl glucoside with production of either maltase, α-methyl glucosidase or sucrase. In the strains containing the gene *MG* without *MA*, growth on α-methyl glucoside elicited a homologous response (production of α-methyl glucosidase), and a hetero-response (production of a sucrase). The growth on α-methyl glucoside failed to endow these strains with ability to ferment maltose. The strains of this genotype were incapable of responding to maltose with production of maltase, α-methyl glucosidase, or sucrase. Strains containing both *MA* and *MG* responded to both maltose and α-methyl glucoside with sucrase synthesis. In these strains maltose also elicited α-methyl glucosidase as well as maltase activity. When the cells of these strains were grown on α-methyl glucoside, they fermented the latter but not maltose on contact. They proved able, however, to adapt themselves to maltose more rapidly after growth on α-methyl glucoside than after growth on glucose.

The observed effects of the single gene changes in genotype *MG MA su* on the response pattern of the strains to α-glucosides are summarized in the accompanying table.

Influence of Single Substitutions of *MG* and *MA* in the Genotype *MG MA su* by the Recessive Alleles *mg* and *ma*

Gene alteration	Responses elicited by α-glucosides: Maltose			α-Methyl glucoside	
	Maltase	Sucrase	α-Methyl glucosidase	Sucrase	α-Methyl glucosidase
MG replaced by *mg*	+	+	−	−	−
MA replaced by *ma*	−	−	−	+	+

+, signifies that the production of the enzyme in response to the inducer was not markedly altered by the noted genic change.

−, signifies that the genic change noted was associated with a large or complete loss of the ability to produce enzyme in response to the inducer.

Thus it may be inferred that *MA* controls the ability of the cells to respond heterologously as well as homologously to maltose, while *MG* controls their ability to respond heterologously as well as homologously to α-methyl glucoside. It has been attractive to consider that yeast α-glucosido-hydrolases (maltase, α-methyl glucosidase, and gluco-sucrase) derive from a common precursor[3]. On the view that there exists a one-to-one relation[4] between a gene and an enzyme, we might assume that gene *MA* with maltose directs the conversion of the precursor into maltase, and that gene *MG* with α-methyl glucoside directs the conversion of the precursor into α-methyl glucosidase. An economical account of the control of heterologous inductions by genes *MA* and *MG* would be afforded by the assumption that primary enzyme products of these genes (maltase and α-methyl glucosidase respectively) may be further converted by the cell into other glucosidases.

Reversible Oxidation of Glucose by Glucose Dehydrogenase

Ox liver has been shown to contain an enzyme, glucose dehydrogenase, which catalyses the reaction[1,2]:

$$\text{Glucose} + \text{diphosphopyridine nucleotide} \rightleftharpoons \text{gluconate} + \text{reduced diphosphopyridine nucleotide.} \qquad (1)$$

This enzyme has now been purified approximately 125-fold, starting from an aqueous extract of ox-liver acetone powder. The purification procedure consists of ammonium sulphate fractionation, precipitation of inactive protein by lead acetate and acidification, and adsorption on and elution from calcium phosphate gel. The purified enzyme has been found to be active with both diphosphopyridine nucleotide and triphosphopyridine nucleotide; but the reaction-rate with the latter is approximately one-half of that obtained with the former.

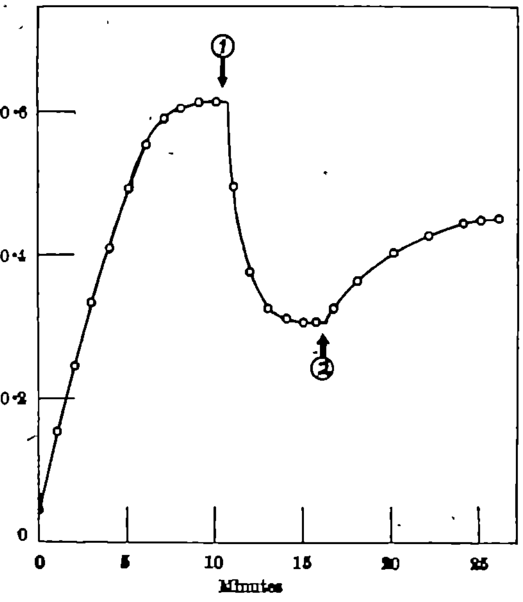
The enzyme has been used for studying the mechanism of oxidation of glucose to gluconate. This oxidation has been shown in other systems to proceed via the gluconolactone both chemically[3] and biologically[4]. Assuming that at *p*H 7·0 $E_0{}^1$ is − 0·43 V.[5,6], reaction (1) can be calculated to have an equilibrium constant of approximately 10^5. Thus, starting with unit concentrations of gluconate and reduced pyridine nucleotide, the reaction could proceed only to the extent of converting 0·3 per cent of the gluconate to glucose. However, if gluconolactone is an intermediate in the oxidation, then reaction (1) may represent the sum of the following reactions:

Glucose + diphosphopyridine nucleotide ⇌ gluconolactone + reduced diphosphopyridine nucleotide. (2)

Gluconolactone + H_2O ⇌ gluconic acid. (3)

Gluconic acid ⇌ gluconate + H^+. (4)

Since at neutral *p*H the major free-energy change in the above series of reactions occurs in reaction (4), it is probable that reaction (2) results in a comparatively small free-energy change and may therefore be reversible. A similar suggestion for the oxidation of glucose phosphate to phosphogluconic acid has been made by Lipmann[7]. The validity of this hypothesis was shown by the oxidation of reduced diphosphopyridine nucleotide and the formation of an equivalent amount of reducing sugar on incubation of glucose dehydrogenase, δ-gluconolactone, and reduced diphosphopyridine nucleotide. Reaction (2) has been followed in both directions by determination of the change in absorption at 340 mμ, as is shown in the accompanying graph. From a series of such experiments, the equilibrium constant for reaction (2) has been calculated to be approximately 15 at *p*H 6·7.



Reversibility of the reaction catalysed by glucose dehydrogenase (reaction 2). Reduction of diphosphopyridine nucleotide and oxidation of reduced diphosphopyridine nucleotide determined spectrophotometrically at wave-length 340 mμ. Quartz cells, *d* = 1 cm. Reaction mixture contained 2·2 millimoles of phosphate buffer, 0·965 micromoles of diphosphopyridine nucleotide, 0·1 c.c. of glucose dehydrogenase (10 mgm. protein per c.c.), and 20 micromoles of glucose in a total volume of 2·9 c.c. At arrow 1, 315 micromoles of δ-gluconolactone added. At arrow 2, 20 micromoles of glucose added. *p*H just prior to the addition at arrow 2, 6·7

It should be noted that, since reaction (3) has also been shown to be reversible[8,9], reduction of gluconate to glucose at high hydrogen ion concentrations is also theoretically possible. In this connexion it has been observed that incubation of gluconic acid with the enzyme and reduced diphosphopyridine nucleotide at *p*H 3·5 results in a slow but significant oxidation of reduced diphosphopyridine nucleotide, this oxidation being reversed by the addition of glucose.

From the equilibrium constant determined for reaction (2), from the equilibrium constant calculated from the data of Levene and Simms[9] for hexonic acids and their corresponding lactones for reaction (3), and from the dissociation constant of gluconic acid (*p*K, 3·78[10]), the potential ($E_0{}^1$) at *p*H 7·0 for the system glucose ⇌ gluconate can be estimated to be about − 0·43 V. This is in agreement with the value cited in the literature[5,6]. Further details of the purification and properties of ox liver glucose dehydrogenase will be published at a later date.

We wish to thank Dr. Severo Ochoa for his interest in and encouragement of this work.

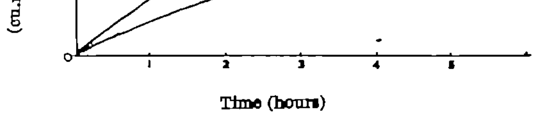
Glucose, Glutamate and Succinate Oxidation in Brain

THERE have, for some time, been difficulties in interpreting the role of glutamate in brain metabolism and its relation to glucose oxidation[1–4]. Weil-Malherbe[2] has adduced evidence to show that, in brain, summation of oxidations occurs if glucose and glutamate are used together as substrate. Krebs and Eggleston[5] have shown that the diffusion of potassium from brain cells *in vitro* is only fully prevented if both glucose and glutamate are present in the medium. On the other hand, Furchgott and Shorr[6] have found that at low oxygen tensions the addition of succinate to brain depresses the normal metabolic activities of the tissue, despite the fact that an increase in oxygen uptake occurs. Our investigations have given rise to certain considerations which seem relevant to this problem.

The early addition of glucose to a preparation of minced guinea pig brain in Krebs–phosphate–Ringer solution produced a substantial increase in oxygen uptake. Later addition, however, produced a very much smaller increase, and addition after three hours none whatever. The addition in the same way of glutamate or succinate produced a much greater increase in oxygen uptake than did glucose, and an almost constant rate of oxidation was maintained for several hours. This effect was obtained even if the glutamate was added after five hours. If glucose was added at any time to a preparation already respiring in succinate or glutamate, no increase in the oxygen uptake of the system was produced. This finding is incompatible with the observations of Weil-Malherbe[2], which show summation of oxidations under these conditions. On the other hand, the addition of glutamate to a preparation already respiring in glucose did produce an increase, but the new rate of oxidation was only equal to that occurring in glutamate alone. The same results were obtained with succinate. The addition of glutamate to a preparation already respiring in succinate produced an increase in oxygen uptake, even though previous addition of glucose to this preparation produced no increase. If succinate was added in the same way to a preparation respiring in glutamate, an increase in the oxygen uptake was also produced. These results are summarized in the accompanying graph.

Those observations suggest that the mechanisms involved in the oxidation of glutamate or succinate are considerably more stable than those involved in the oxidation of glucose. The stability of the latter mechanisms appears to be directly dependent upon the availability of substrate, for if the tissue is permitted to respire in Krebs–phosphate–Ringer solution alone, it rapidly loses its capacity to oxidize added glucose. However, even after several hours respiration in Krebs–phosphate–Ringer solution alone, the capacity of the tissue to oxidize succinate or glutamate is only slightly impaired. The increase in oxygen uptake following the addition of glucose appears, moreover, to bear some relationship to the rate of respiration prevailing at the time of addition, while the increase following the addition of glutamate or succinate seems to be independent of the prevailing rate of respiration.



(1) Guinea pig brain respiring in Krebs–phosphate–Ringer solution containing glucose. (2) Effect of adding glutamate to brain respiring in glucose. (3) Brain respiring in Krebs–phosphate–Ringer solution containing glutamate, but no glucose. (4) Effect of adding glucose (marked by arrow) to brain respiring in glutamate. (5) Effect of adding succinate to brain respiring in glutamate.

All experiments were carried out in Warburg flasks, at 37·5° C., in air, at 100 shakings per minute. The brain mince was produced by pressing the brain once through a 60-mesh sieve. 50–150 mgm. of tissue in Krebs–phosphate–Ringer solution was used in each flask, the final fluid volume being 5 ml., and the gas volume about 25 ml. The carbon dioxide was absorbed with potassium hydroxide paper. The final concentration of added glucose in each case was 0·2 per cent, that of glutamate or succinate 0·02 molar. The time between the death of the animal and the first reading was 20–30 min. Oxygen uptakes are uniformly calculated for 100 mgm. of tissue

The fact that the addition of glutamate to a preparation already respiring in succinate produces a further increase in oxygen uptake indicates that the mechanisms involved in the oxidation of glutamate to α-keto-glutarate and succinate are not inhibited by the concentration of succinate used.

The addition of glucose to a preparation containing the same concentration of succinate might similarly be expected to produce an increase in oxygen uptake. That no such increase occurred, no matter when the glucose was added, suggests that, under these conditions, glucose oxidation does not take place. Direct estimations of the amount of glucose consumed in the course of each experiment confirm this view. Further corroborative evidence is seen in an observation reported by Lipsett and Crescitelli[7]. These workers found that the addition of potassium chloride increased the oxygen uptake of rat brain slices respiring in glucose, but that this potassium effect was abolished in the presence of glutamate, succinate and certain other members of the tricarboxylic acid cycle. If, as our findings suggest, glucose is not oxidized in the presence of glutamate or succinate, then a potassium effect can scarcely be expected. It is difficult to see in what way an increase in the concentration of members of the tricarboxylic acid cycle can inhibit glucose oxidation; but it is possible that this phenomenon represents a mechanism by which the rate of glucose oxidation in brain is regulated.

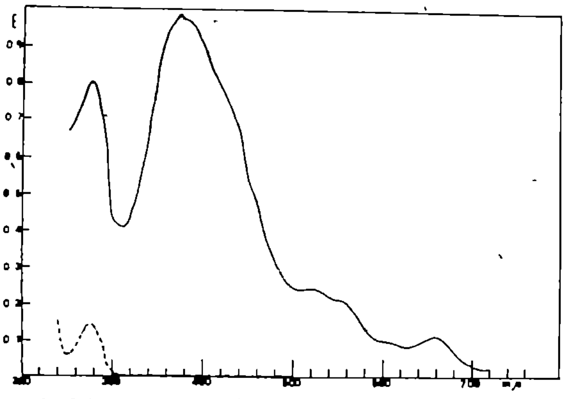
Spectrophotometric Determination of Hæmoglobin in Blood

A VARIETY of methods has been used for the determination of hæmoglobin in blood. They are based on (i) oxygen absorption[1], (ii) the iron content[2], or (iii) the transformation of the hæmoglobin to carboxyhæmoglobin[3], cyanhæmatin or acid hæmatin, which are then estimated colorimetrically[4] or spectroscopically[5,6].

The method described here is a development of the acid hæmatin procedure and involves the determination of the intensity of light absorption by the pigment using a Unicam spectrophotometer. The full absorption spectrum of the acid hæmatin (0·02 ml. blood in 0·1 *N* hydrochloric acid) has been determined in the ultra-violet and visible regions.



0·02 ml. blood in 10 ml. N/10 hydrochloric acid : ———, blood ; —·—·, serum

The absorption curve (see graph) shows maxima at 280 mμ, 372·5 mμ, 510 mμ and 660 mμ, and minima at 310 mμ, 500 mμ and 630 mμ. (Other characteristics of this spectrum are that $E(372\cdot5)/E(310) = 2\cdot50$ and that the intensities of absorption at 350 mμ and 408 mμ are the same.) The maximum at 372·5 mμ is used for the assay; and by calculation based on the iron content of the pigment, the E(1%,1 cm.) value was found to be 32·3. The conversion factor 15·5 was then derived to give the percentage of hæmoglobin in blood.

The plasma proteins and other blood constituents do not absorb in this region. Again, oxalate does not interfere, though citrated blood gives a slightly higher result. The acid hæmatin appears to be stable for at least six days, thus permitting the collection of a large number of samples prior to assay.

The procedure is as follows. 0·02 ml. of blood collected in a micro-pipette from a finger prick is added to 10 ml. of 0·1 N hydrochloric acid in a test-tube and shaken. After at least 10 min., the intensity of absorption of the acid hæmatin solution is measured in the spectrophotometer at 372·5 mμ, using a 1-cm. cell and decinormal hydrochloric acid as compensator. The percentage hæmoglobin in the blood is given by $E(372\cdot5) \times 15\cdot5$.

COMPARISON BETWEEN THE SPECTROPHOTOMETRIC AND WONG'S IRON METHODS

No.	E(372·5)	E(372·5) × 15·5	Wong's method
1	0·990	15·38	15·40
2	0·955	14·80	14·80
3	0·885	13·70	13·90
4	1·025	15·90	15·95
5	0·925	14·38	14·40
6	0·980	15·20	15·10
7	0·900	13·95	14·00

The results obtained by this procedure are reliable and in close agreement with values from the iron determinations; further, the assay requires much less time and manipulation.

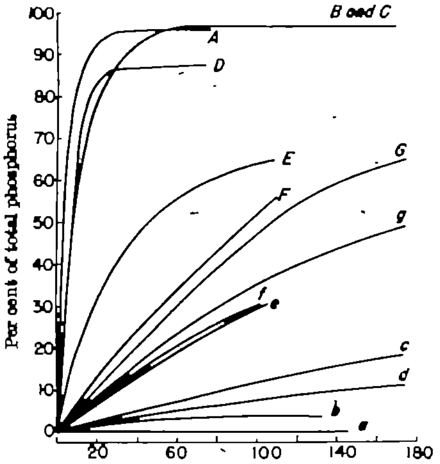
Specific Requirements for the Action of Deoxyribonuclease

THE mechanism of action of pancreatic deoxyribonuclease, now available in the crystalline state[1,2] on highly polymerized deoxypentose nucleic acids is still obscure. The enzymatic attack is known to result in the formation of dialysable oligonucleotides and of a non-dialysable 'core' which, in the case of the nucleic acids from calf thymus[3,4] and wheat germ[5], is characterized by proportions of adenine, and to a lesser degree of thymine, greatly in excess of those encountered in the original substrate. Mononucleotides and inorganic phosphate are not found among the degradation products[3,4], and this precludes the attribution to deoxyribonuclease of functions similar to those of phosphomonoesterases. It could be regarded as a phosphodiesterase of a closely circumscribed, as yet undefinable, specificity. A small number of acidic groups is, in fact, liberated during the digestion[6]. That the attack of an enzyme the action of which consists in the depolymerization of a substance of high molecular weight, exhibiting no easily recognizable periodicity of constituent sequence, must follow an intricate pattern is clear: every break of the original molecule produces substrates that are new and different; the enzyme must deal with kaleidoscopic substrate changes.

It appeared of interest to correlate substrate structure and susceptibility to enzymatic attack by studying the rate of disintegration to dialysable fragments, under the influence of crystalline pancreatic deoxyribonuclease, of deoxypentose nucleic acid preparations of different states of integrity. All preparations were derived from the highly polymerized deoxyribonucleic acid of calf thymus. Approximately 0·2 per cent solutions of the substrates in distilled water were, in some cases after the addition of 0·01 per cent of crystalline deoxyribonuclease, placed in small 'Cellophane' bags and incubated at 37°, with simultaneous dialysis against the ten- to twenty-fold volume of 0·02 M borate buffer of pH 7·3, which was 0·02 M with respect to magnesium sulphate and contained 0·001 per cent of ethylmercurithiosalicylate. Control experiments, in which both enzyme and magnesium were omitted, also were carried out; they are not included here, since no dialysable fragments occurred under these conditions. The rate of appearance of dialysis products was followed spectroscopically and, more conveniently, by determination of the total phosphorus in the dialysates.

For the presentation of the results in the accompanying diagram, the amounts of dialysable nucleotide phosphorus (as percentage of total substrate phosphorus) are plotted against time. The curves marked with capital letters indicate experiments carried out in the presence of both deoxyribonuclease and magnesium ions; small letters refer to the corresponding experiments performed without enzyme, but with magnesium ions present. The following substrates were employed: A, intact[7] deoxyribonucleic acid; B, preparation A kept at pH 11·8 (1 hr., 25°) and readjusted to pH 7·5; C, preparation A kept at pH 2·95 (1 hr., 25°) and readjusted to pH 7·5 (it should be noted that preparations B and C are capable of re-polymerization, regaining considerable, though highly thixotropic, viscosity[7]); D, preparation A kept in glycine buffer of pH 2·86 (24 hr., 37°), neutralized by dialysis against borate buffer of pH 7·3 and recovered by the evaporation in a vacuum of its frozen solution, fter thorough dialysis against water (this substance till contained all nitrogenous constituents in unhanged proportions and ratios[4]); *E*, preparation *A* cept in glycine buffer of *p*H 2·3 (24 hr., 37°) and lialysed and recovered as described for *D* (this substance retained 48 per cent of the purines originally resent; the pyrimidine composition was unhanged); *F*, preparation *A* suspended in dilute ydrochloric acid of *p*H 1·7 (26 hr., 36°) and dialysed nd recovered as described for *D* (this substance ontained about 13 per cent of the purines originally resent—8 per cent of the adenine, 24 per cent of he guanine; the pyrimidine composition was unhanged); *G*, this is the non-dialysable degradation roduct described recently as "apurinic acid"[8], in vhich a deoxypentose nucleic acid has been completely deprived of its purine constituents without mpairment of its original inter-pyrimidine ratios. t will be understood that in preparations *E*, *F* and *G* he position in the nucleic-acid chain of the missing urine nucleotides is marked by reactive aldehydo groups.



Action of crystalline pancreatic deoxyribonuclease + magnesium ions (curves marked with capitals) and of magnesium ions alone (curves marked with small letters) on intact calf thymus deoxyribonucleic acid (curves *A* and *a*) and on products of its denaturation (curves *B*, *C*, *D* and *b*, *c*, *d*), or partial degradation (curves *E*, *F*, *G* and *e*, *f*, *g*). See the text for the experimental arrangement and the composition of the substrates

The denaturation of the nucleic acid, that is, the nterference with its physical qualities, as must have occurred in preparations *B*, *C* and particularly *D*, loes not, by itself, materially impede the enzymatic reakdown. (Compare curves *A*, *B*, *C*, *D*.) The letachment of even a portion of the purines (curves *E* and *F*) or their complete removal (curve *G*) acts, owever, as a block. It is apparent that the enzyme equires the full complement of purines to be present, lthough it cannot yet be decided whether the latter re necessary as the points of attachment or because f specificity characteristics of deoxyribonuclease imilar to those discussed recently with respect to ibonuclease[9]. In addition, the interference with the mphoteric properties of the nucleic acid and the reation of aldehydo groups, both consequences f the removal of purines, may also be held esponsible.

The peculiar effects of magnesium ions in the bsence of enzyme (curves marked with small letters) re not without interest. The ability of this divalent cation to bring about a non-enzymatic disintegration appears to be in an inverse relationship to the susceptibility of the particular substrate to enzymatic attack. The intact nucleic acid is broken rapidly by the enzyme in the presence of magnesium (curve *A*); the cation alone has no effect (curve *a*). On the other hand, in apurinic acid, practically all the work seems to be done by magnesium ions alone (compare curves *G* and *g*). It is not possible to offer an adequate explanation of these findings. The role of magnesium ions in the activation of deoxyribonuclease has been considered repeatedly[1,2,10–13]. The experiments presented here could lead to the surmise that two different types of mutually supporting bonds are opened in the nucleic acid by the complete enzyme system: one broken by the deoxyribonuclease, the other affected by magnesium ions. However, attempts to demonstrate two phases of degradation by separating them in time were not successful. When a solution of intact deoxypentose nucleic acid in physiological saline (0·05 *M* with respect to sodium citrate) was treated with deoxyribonuclease at 37° for 18 hr., a considerable drop in viscosity was observed; but the addition of magnesium ions to the solution, after it had been freed of enzyme and citrate, failed to produce dialysable fragments.

These experiments and related studies will later be presented in detail. This work has been supported by research grants from the National Institutes of Health, United States Public Health Service, and from the Rockefeller Foundation.

Mould Lipase: Effect of Addition of Vitamins and Sterol to the Cake Medium on the Growth and the Activity of the Lipolytic Mould

WE have isolated a strain of *Aspergillus niger* from the castor bean which shows high lipolytic activity. We have found that this lipolytic strain grows well in a cake medium containing 15 per cent oil-free groundnut cake, 10 per cent fresh groundnut oil and 200 c.c. water, adjusted to *p*H 4·2 and incubated at 35° C. for four days. The effect of addition of substances like vitamin B_1, vitamin B_2, ascorbic acid, α-tocopherol, digitonin and cholesterol to the cake medium on the activity of the lipolytic mould has been studied.

The strain of *A. niger* was inoculated on the cake medium in different conical flasks; the medium was autoclaved for 15 min. under 10-lb. pressure. The mats were removed after four days incubation and the lipase prepared according to Ramakrishnan and Nevgi's method[1]. The hydrolysis of fresh groundnut oil was carried out using the lipase and disodium hydrogen phosphate – citric acid buffer of *p*H 6·2. Each set of the experiments consisted of 1 c.c. groundnut oil, 5 c.c. water, 2 c.c. phosphate buffer, 0·1 gm. mould lipase and a few drops of toluene in a conical flask incubated for 24 hr. at 37° C. Blanks always accompanied the samples. After the period of incubation, the contents were taken out and titrated against *N*/10 sodium hydroxide after the addition of 25 c.c. of neutral alcohol and warming for some time. All readings were taken under sterile conditions. The difference between the sample and the blank will give the activity of lipase in terms of c.c. of *N*/10 sodium hydroxide. The results are given in Table 1.

Table 1

Amount of the substance added (mgm.)	Difference in c.c. of *N*/10 sodium hydroxide between the sample and blank in case of lipase obtained from the mould grown in the medium containing: Cake only	Cake + vit. C.	Cake + vit. B_1	Cake + vit. B_2	Cake + α-tocopherol	Cake + digitonin	Cake + cholesterol
0·0	22·6	—	—	—	—	—	—
1·0	—	22·8	22·9	24·3	23·6	No growth	27·8
5·0	—	25·7	25·8	28·8	27·9	,,	35·3
10·0	—	23·1	23·5	25·1	24·2	,,	26·1
20·0	—	18·5	19·2	21·9	22·1	,,	24·2

From Table 1, it can be seen that the lipolytic mould does not grow in the medium containing digitonin. It grows very well in the medium containing cholesterol, vitamin B_2 or α-tocopherol. The lipolytic activity is very high in the case of the mould grown in the medium containing 5·0 mgm. of cholesterol. Vitamin B_2, α-tocopherol and cholesterol increase the activity of the lipolytic mould when added to the medium at a concentration of 5 mgm. per 200 c.c.

Table 2

*p*H	Difference in c.c. of *N*/10 sodium hydroxide between the sample and the blank in case of lipase from mould grown in the medium containing: Cholesterol	Vitamin B_2	α-Tocopherol
3·6	12·3	10·5	7·2
4·8	19·2	16·2	9·8
5·2	30·6	22·6	15·2
5·7	36·9	29·3	19·1
6·2	35·3	25·8	27·9
6·8	29·6	18·5	15·2
7·2	22·5	10·2	8·3

In order to see whether the optimum *p*H for the activity of the mould lipase is affected by adding these substances, the hydrolysis of groundnut oil was carried out using these lipases and disodium hydrogen phosphate – citric acid buffer of different *p*H. The results are shown in Table 2. It was found that the optimum *p*H slightly changes (5·7–6·2), depending upon the nature of the substance added to the medium.

From these observations, it can be seen that addition of cholesterol, vitamin B_2 and α-tocopherol to the medium enhances the activity of the lipolytic mould, and the optimum *p*H for its activity changes with the nature of the substance added to the medium.

Details of this investigation have been submitted to *Enzymologia*.

Our thanks are due to the Indian Council of Medica Research for having awarded a research fellowship t one of us (C. V. R.) to carry out this investigation.

Thermal Conductivity of Human Fat and Muscle

UNTIL recently, it was generally believed tha human subcutaneous fat serves as an effectiv insulator. Nevertheless, we have been unable t trace any record of actual measurements of th thermal conductivity of human tissue. Bordier[1], i 1898, made experiments on beef tissue by a satisfactory method. He found the muscle to conduc 1·8 times as well as the fat. A few other less satisfactory measurements were made about the sam time with similar results. The human case wa assumed to be similar.

No further experimental work seems to have bee published until 1938, when Hardy and Soderstrom[2] in a paper dealing with human calorimetry, state that they had measured the conductivity of bee tissue, and found for fat 0·00049 cal.cm./cm.^{2}sec. °C and for muscle 0·00047. They base on this result denial that a fat person has more insulation agains cold by reason of this fat than a thin person.

Clearly, measurements were called for on huma tissue, and these we have undertaken, using a instrument devised by one of us[3], a thermo electr heat-flow disk. Pieces of fat and muscle, abou 1 cm. thick and 5 cm. × 5 cm. or more in area, ar placed between two thin glass plates. In the centr of one side of the specimen is a heat-flow disk an a thermo-junction connected in opposition to a simila junction on the other side of the specimen. Two suc assemblies, one with fat, the other with muscle, wer placed in an incubator with a woven-wire resistanc heating-mat sandwiched between them. A curren of heat (about 40–50 kcal./m.^{2}hr.) could thus b caused to flow through the two specimens. Th flow is at right angles to their planes in the centr where it is measured by the disk, while the differenc of temperature between the two sides of the specime is measured by the couples. The thermal conductivit is given by $\frac{\text{heat-flow} \times \text{thickness}}{\text{temperature-difference}}$, and is expresse in cal.cm./cm.^{2}sec. °C.

Specimens of human tissue were obtained fron hospital post-mortems, and fresh-killed beef from th Caledonian Market. The last five samples of huma tissue tested gave the following results:

Date	Fat	Muscle	Ratio
11.6.1951	0·000445	0·00104	2·33
	0·000415	0·00045	1·08
14.6.1951	0·00047	0·00122	2·6
20.6.1951	0·00047	0·00095	2·02
22.6.1951	0·000385	0·000775	2·0
	0·000445	0·00108	2·42
Mean	0·000438	0·00092	

The figures for 11.6.1951 refer to two separate tissu pairs from different bodies, those for 22.6.1951 ar for a pair from the same body, each piece being measured at two points.

The values for beef were:

Date	Fat	Muscle	Ratio
22.5.1951	0·000484	0·00057	1 18
28.5.1951	0·000495	0 00046	0·93
18.6.1951	0·000487	0 00097	2·0
Mean	0·000489	0 00067	

It seems legitimate to conclude from the above figures that fat is a better thermal insulator than muscle. The latter, however, is very variable when measured dead; the near-constancy of the figures for fat shows that the variations in those for muscle are due to the material and not the method. Preparations kept for a day or two at room temperature showed very slight change in the fat, but large changes in the muscle, usually an increase. The discrepancy between the results of Bordier and Hardy and Soderstrom with beef tissue is thus easily explained. The agreement with the latter's figures for fat is very close.

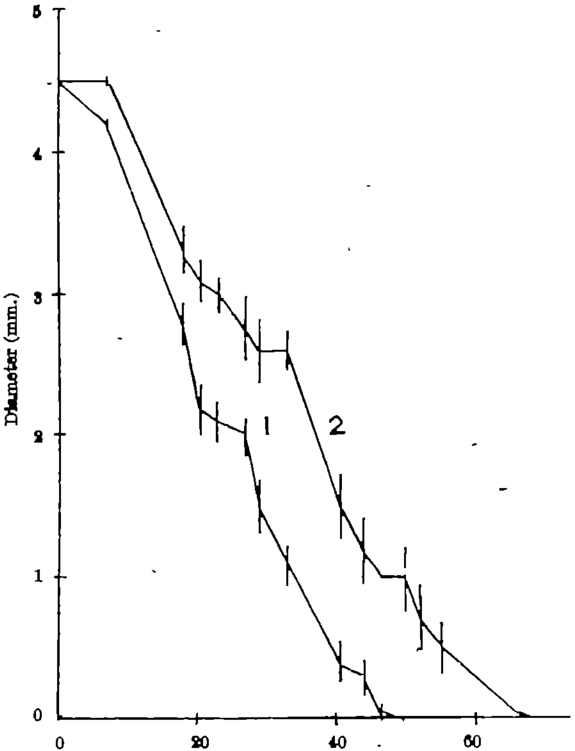
Electric Shock and the Regeneration of the Corneal Epithelium of Rabbits

IT was considered of interest to discover the effect of electric shock on epithelial regeneration, since there are indications that mitotic activity is profoundly affected in shock conditions[1]. In order to obtain quantitative information, artificially produced lesions of the corneal epithelium of rabbits were regarded as a suitable object. With the aid of Nižetić's corneal trepan and a small lancet, practically identical lesions were made in each cornea. Each of them had a diameter of 4·5 mm. and for convenience was dyed with uranin (1 per cent); thus it was easy to measure two diameters at right angles to each other. There were two groups, each consisting of four animals, and both eyes of each animal were operated on. One group of animals was stressed by electrical injury three times a day during observation, by applying alternating current of 50 c./s. and 45 V. for one second. Convulsions lasted for nearly 60 sec., unconsciousness up to 180 sec. Except during the convulsions, the sensitiveness of the cornea was normal. The other group served as a control. To obtain information as to the speed of regeneration, the extent of the two diameters of each lesion was measured with a circle every three hours during the day-time.

Beginning from the eighteenth hour after the operation, the difference between the two groups of animals became significant. The accompanying graph constructed from the average means, including standard errors, against time, shows the diminution of the diameters of the lesions in the two groups of rabbits. It is evident that the regeneration of the epithelium of the shocked animals is inhibited in comparison with the regeneration of controls. The complete regeneration of the shocked animals was retarded by more than half a day, that is to say, by about 25 per cent of the normal period. Comparing both curves of the graph, a linear function may be possible in either case, especially when we take into account the existence of an initial lag due to the cocainization of the eye.



Diameters of the corneal lesions. (1) Control group; (2) shocked group

As to the cause of inhibition of regeneration, there are indications that sugar metabolism is affected; but other disturbances may also be involved.

Vegetative Propagation from the Broccoli Curd after Suppression of Flowering

IN the course of an inspection of early varieties of autumn cauliflower and broccoli grown for seed production in Cyprus during 1946, it was observed in certain crops that after the inflorescence had formed very few flower buds developed. Suppression of flower development also occurred in a seed crop in the Scilly Isles later that year, and in a glasshouse in Devon, where selected broccoli plants were being seeded.

Further observations were continued in the case of the glasshouse crop. These plants had been transplanted from the field when the curds were visible. The curds were broken up by the elongation of the inflorescence stalks, and flowers developed. On certain plants a few early flowers which had been pollinated continued to develop and formed seed pods; but later buds turned yellow in colour, shrivelled and dropped before opening. At the same time the bracts on the inflorescence stalks started rapid growth, eventually forming a dense mass, and finally, after a few weeks, leafy shoots were observed to develop.

It was found that these vegetative shoots could be rooted[1] in sand and produced plants which did not appear to differ in any respect from those raised from seed, and which formed curds at the normal season for the variety.

The following year a series of curd cuttings were rooted and grown on until the first flower buds were opening, when some of the plants were transferred to a glasshouse where the temperature ranged from 60° to 80° F. The remainder of the plants were kept in the unheated glasshouse where the temperature at the time of the year ranged from 40° to 70° F. After four days the flower buds on the plants at the higher temperature were observed to be aborting, with rapid development of bracts. The buds on the plants at the lower temperature opened normally, were pollinated and produced seed.

The results appear to follow closely those obtained with Danish Ball Head cabbage, in which flowering is suppressed at an average temperature of 60° F.[2].

When breeding cross-pollinated species it is often desirable to be able to return to the original parent material. It is also of considerable value to be able to establish clones. This has not previously been achieved with cauliflower and broccoli. By removal to a temperature of 70°–80° F. for a relatively short period, plants which have already formed curds can be returned to a vegetative state. Large numbers of plants can then be obtained from a single curd by rooting the leafy shoots which develop after flower suppression at the high temperature.

Could an Arms-Race end Without Fighting?

Dr. L. F. Richardson has attempted (*Nature*, Sept. 29, p. 567) to foretell the result of the arms-race by means of differential equations. While his conclusions are most interesting, has he investigated the effect of assuming slightly different initial equations which would appear at least as reasonable as those he adopts? The following argument suggests a somewhat altered form for his equations (1) and (2).

There would not appear to be anything particularly absolute in reactions to any given arms expenditure; what one generation considers heavy, a succeeding generation considers but slight. Hence all terms in the equations should imply influences relative to the general rate of expenditure, not to the absolute rate. This implies that the equations should be homogeneous in x and y—thus throwing doubt, in the case of equation (1), on the terms $ky\{1 - \sigma(y - x)\}$ and g. Since Dr. Richardson assumes $g = 0$, this term need not be discussed further; but consider the effect on the former term of a general increase of arms expenditure when, initially, $\{1 - \sigma(y - x)\} = 0{\cdot}5$. A doubling of expenditure by both sides would then reduce the 'defence' reaction of the first side to zero—a result which seems scarcely likely.

A more reasonable form of equation (1) would seem to be:

$$\frac{dx}{dt} = ky - \sigma(y - x) - \alpha x. \qquad (a)$$

Assuming that a similar equation, with identical coefficients, governs the rate of increase of expenditure of the second side, the two simultaneous equations lead simply to:

$$x + y = (x_0 + y_0) \exp\left[\,(k - \alpha)(t - t_0)\,\right] \qquad (b)$$

$$\frac{x - y}{x + y} = \frac{(x_0 - y_0)}{(x_0 + y_0)} \exp\ \left[2(\sigma - k)(t - t_0)\right], \qquad (c)$$

where x_0 and y_0 are the values of x and y at time t_0. If at any time (say, when $t = t_0$), $(x + y)$ is increasing, then $k > \alpha$, and $(x + y)$ continues to increase exponentially. If $\sigma > k$, that is, if the 'submissiveness' coefficient σ overrides the 'defence' coefficient k, the relative difference in arms would increase, again exponentially (equation c), and one might perhaps presume that there would be no war. If the reverse were true, the armed strengths of the two sides would become relatively almost equal, and one would probably regard war as increasingly inevitable.

On this analysis, therefore, an arms-race would lead to war unless there were an appreciable degree of 'submissiveness'—a result which is perhaps scarcely surprising.

M. R. Horne

48 Mill Road,
Royston, Herts.

Mr. M. R. Horne's letter should be welcomed as raising questions that will not be understood until they have been argued. The question at issue may be stated thus.

Let us name $\dfrac{\partial}{\partial y}\left(\dfrac{dx}{dt}\right)$ the 'effective' defence-coefficient. Now, on Mr. Horne's hypothesis,

$$\frac{\partial}{\partial y}\left(\frac{dx}{dt}\right) = k - \sigma,$$

which can have either sign, but cannot change sign. But on Richardson's (1939) hypothesis,

$$\frac{\partial}{\partial y}\left(\frac{dx}{dt}\right) = k\,\{1 + \sigma\,(x - 2y)\},$$

which can change sign according as $2y - x \gtrless 1/\sigma$. The common saying that 'all bullies are cowards' suggests that a change of sign occurs somewhere. However, the present equations are intended to represent the behaviour, not of individuals, but of nations. The effective defence-coefficient of Germany has been estimated from statistics of warlike expenditure, and was found to be positive during 1908–14, negative during 1920–30, and positive again during 1930–39. The discussion of the submissive interval is at present published only in microfilm[1].

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Mr. F. C. Bawden, F.R.S.: "The Scientific Basis of Medicine, 16, Current Knowledge on Nature of Viruses".* (Further Lectures on December 4, 6 and 11.)

ROYAL AERONAUTICAL SOCIETY (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. H. H. Gardner: "Structural Problems in Advanced Aircraft".

Friday, November 30

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Anniversary Meeting.

COUNCIL FOR THE PROMOTION OF FIELD STUDIES (at Goldsmiths' Hall, Foster Lane, Cheapside, London, E.C.2), at 5 p.m.—Annual General Meeting; Dr. Arthur Raistrick: "The Bone Recorder and other Archæological Remains on Malham Moor".

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. S. Y. Chung and Prof. H. W. Swift: "Cup-Drawing from a Flat Blank—Experimental and Analytical Investigations".

INSTITUTION OF ELECTRONICS, NORTH-WESTERN BRANCH (at the College of Technology, Manchester), at 7 p.m.—Dr. T. Kilburn: "The Use of Cathode Ray Tubes in Digital Computing Machines".

Saturday, December 1

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. A. D. Lacaille: "Stone Age Tools".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PRINCIPAL (graduate of a university in the United Kingdom, with first- or second-class honours, or higher degree, in science or engineering) OF THE NEATH TECHNICAL COLLEGE—The Director of Education, County Hall, Cardiff (November 30).

ASSISTANT, Grade B, IN PHYSICS—The Principal, Royal Technical College, Salford (December 1).

ASSISTANT MASTER (in the Secondary Technical School for Boys) to teach CHEMISTRY throughout the school—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (December 1).

ASSISTANT LECTURER IN APPLIED OPTICS—The Registrar, College of Technology, Manchester 1 (December 3).

SENIOR ASSISTANT ENGINEER in the Generation (Operation) Department at Divisional headquarters—The Divisional Secretary (Establishments), British Electricity Authority, North-Eastern Division, Carliol House, Newcastle-upon-Tyne 1 (December 3).

WATER SUPPLY ENGINEER in the Water Works Sub-Department of the Public Works Department, Ceylon—The High Commissioner for Ceylon in the United Kingdom, 13 Hyde Park Gardens, London, W.2 (December 5).

ADVISORY OFFICERS (with a recognized degree in botany or agriculture and a leaning towards grassland work) at the Sports Turf Research Institute—The Secretary, St. Ives Research Station, Bingley, Yorks. (December 8.)

AERODYNAMICISTS, PHYSICISTS and ENGINEERS (Scientific Officer (Ref. C.678/51A) and Experimental Officer (Ref. C.679/51A) grades), at a Ministry of Supply research establishment in Hampshire, for work concerned with problems of heat transfer, aerodynamics, projects and performance in the increasingly important field of gas turbine research—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No. (December 8).

LECTURER IN PHYSICS—The Registrar, The University, Sheffield (December 8).

ASSISTANT CIVIL ENGINEER in connexion with the design, maintenance and construction of dock and harbour works—The Secretary, Tyne Improvement Commission, Bewick Street, Newcastle-upon-Tyne 1 (December 14).

EXPERIMENTAL OFFICER in the Mechanical Engineering Research Organization (Department of Scientific and Industrial Research), for research work on the plastic deformation of metals occurring in commercial processes such as rolling, deep drawing, forging, pressing, wire drawing, tube drawing, extrusion, etc.—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.680/51A (December 15).

LECTURER OR ASSISTANT LECTURER (with a University degree in agriculture, preferably with honours, or postgraduate work in Crop Husbandry and/or Horticulture) IN AGRICULTURE (Crop Husbandry), and a LECTURER OR ASSISTANT LECTURER (with a University degree in either Chemistry, Geology or Agriculture with postgraduate experience in Pedology) IN PEDOLOGY, in the Faculty of Agriculture, University College of Khartoum—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (December 15).

LECTURERS IN ELECTRICAL ENGINEERING, CIVIL ENGINEERING, MECHANICAL ENGINEERING, NAVAL ARCHITECTURE, PRODUCTION ENGINEERING, GEOLOGY, APPLIED CHEMISTRY, METALLURGY, MATHEMATICS, OPTOMETRY, APPLIED PHYSICS, PHILOSOPHY (special reference to scientific method), ECONOMICS, ECONOMIC HISTORY, ARCHITECTURE, and ENGLISH, at the New South Wales University of Technology—The Agent-General for New South Wales, 56–57 Strand, London, W.C.2 (December 15).

RESEARCH OFFICER (Physical Chemist, Infra-Red Spectroscopy) IN THE BIOCHEMISTRY UNIT, Wool Textile Research Laboratory, Melbourne—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 3626 (December 15).

SCIENTIST, Grade I, at the Central Research Establishment, Stoke Orchard, Cheltenham, to assist in the supervision of chemical and physical research, fundamental to the carbonization of coal—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/397 (December 15).

SCIENTISTS, Grade II (with a good honours degree in chemistry) at the Laboratories in Leeds and Sheffield—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/398 (December 15).

Senior Scientific Officers and Scientific Officers at Admiralty experimental establishments in the vicinity of London, Greenock, Haslemere, Portsmouth, Rosyth and Weymouth: Physicists (Ref. A.336/50A) capable of undertaking research or development in general physical problems, electronics, acoustics or thermodynamics, Electrical Engineers (Ref. D.367/50A) qualified to undertake research, development or design in telecommunications, radar, electronics, instrumentation or light electrical mechanisms, and Mechanical Engineers (Ref. C.631/50A) capable of design, development or research work in light mechanisms, structures or hydrodynamics—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No. (December 15).

Senior Scientific Officers at a Ministry of Supply experimental establishment in Southern England for (*a*) research work in connexion with aircraft flight testing, and (*b*) to lead a team in aeronautical research work connected with the development of flight testing and operating technique for helicopters—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4104/51 (December 20).

Lecturer in Animal Husbandry—The Registrar, The University, Liverpool (December 31).

I.C.I. Research Fellowships in Biochemistry, Chemistry, Engineering, Pharmacology or Physics—The Secretary, The University, Edinburgh (March 1).

Aeronautical and Mechanical Engineers (Scientific Officer grade) mainly in the Aerodynamics and Structures Departments of the Royal Aircraft Establishment, South Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.596/51A.

Assistant, Grade B (with honours chemistry degree, and preferably teaching experience to B.Sc. (general) and A.R.I.C. standard), for Chemistry—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford.

Assistant Drilling Engineer (with a degree in mechanical or mining engineering, or equivalent institute qualifications, with practical experience) in the Public Works Department (Geological Survey), Sudan—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Assistant Drilling Engineer 4/161'.

Assistant Lecturer (University graduate in engineering, or equivalent qualification) in Mechanical Engineering—The Principal, College of Technology and Arts, Rugby.

Assistant Physicist at the Hogarth Radiotherapeutic Centre—The Secretary, General Hospital, Nottingham.

Design Engineers to undertake the duties of project engineers, including the design of special plant and equipment and the layout required for efficient manufacturing processes—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs.

Electrical Engineer (Electronic) on the headquarters staff at the London office—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.28544.B.

Electronic Physicists and Engineers (Experimental Officer grade) at a Ministry of Supply research establishment in the South-East of London: Electrical Engineer (Ref. D.491/51A) with experience of aircraft radar installation and maintenance, and a Physicist (Ref. A.336/51A) with experience in the generation and reception of signals in the V.H.F./U.H.F. region, or in the production and handling of short duration pulses—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

Engineer at a Ministry of Supply establishment in Bickley, Kent, to direct the inspection of the preservation, identification and packaging of electrical, mechanical and telecommunications equipments and stores, and to be responsible for general policy and design in this sphere—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.362/51A.

Industrial Chemist to interpret basic chemical research to engineers engaged in the design of chemical plants and to advise on the design of these plants—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs.

Officer-in-Charge (graduate in agriculture, preferably with Ph.D. and with at least five years postgraduate experience in experimental work), Tobacco Research Station, Trelawney, Southern Rhodesia—The Secretary, Tobacco Research Board of Southern Rhodesia, P.O. Box 1909, Salisbury, Southern Rhodesia (apply by air mail).

Pharmaceutical Chemist (with at least ten years practical research and teaching experience) at Lady Hardinge Medical College, New Delhi—The Secretary (Division 5A), Ministry of Health, Savile Row, London, W.1.

Physicists and Engineers (Principal Scientific Officer grade) at Royal Naval Scientific Service research and development establishments in the South of England: Physicists and Electrical Engineers (Ref. A.340/51A) who have specialized in electronic devices and circuitry, and Mechanical Engineers (Ref. C.667/51A) who have specialized in electro-mechanical devices and servo mechanisms—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

Research and Development Engineers and Technical Assistants at the Ministry of Supply Factory, Capenhurst, Chester, to participate in the work of a team engaged in the pilot plant stage of translating physical and chemical research to the plant stage—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs., stating post applied for.

Scientific Officers at the Ministry of Supply Factory at Capenhurst, Chester, to undertake original research of a physical nature directed toward the design and development of an atomic energy factory and to collaborate with the engineering organizations responsible for the building and operation of the factory—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs.

Senior Scientific Officer (Ref. C.669/51A) to lead a section in special investigations chiefly concerning Naval Aviation and related mechanical problems, a Scientific Officer (Ref. A.341/51A) for work connected with out-of-door instrumentation, Experimental Officers (Mechanical Engineers) (Ref. C.668/51A) to assist with the development of special flight-deck equipment for naval aircraft, and an Assistant Experimental Officer (Physicist) (Ref. A.342/51A) to carry out electronic methods of measurements, in which work initial training will be given, in the Naval Aircraft Department of the Royal Aircraft Establishment, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Productivity Team Report. The Hop Industry: Report of a Visit to the U.S.A. and Canada in 1950 of a Productivity Team representing the Hop Industry. Pp. ix+113+35 plates. (London and New York: Anglo-American Council on Productivity, 1951.) 9s. 6d. [109

FURTHER EDUCATION IN THE WELFARE STATE

IN his recent book, "The English Universities and Adult Education" (see *Nature*, November 17, p. 887), Mr. S. G. Raybould takes up first the challenge that the work of the extra-mural departments of the universities of Great Britain should justify its support primarily in terms of the nature of university work, and not on grounds of the value of adult education in general. Accordingly, his first chapter examines the question of university standards. Indeed, he regrets that the challenge has not been presented earlier in a form compelling a reply; but his challenge should certainly stimulate that fresh thought about the nature and purpose of adult education, in relation both to the development of the individual and to social change, which is an urgent need. If at the same time there is further fundamental thinking about the purposes and functions of a university, there should be little danger that any attempt to instil the spirit and method of university teaching into all adult education will fail to meet the essential test which should be applied to any increase in university commitments. This, as Mr. Raybould rightly insists, is not whether educational needs exist which are not being met, but whether they are of a character proper for universities to meet.

In his examination of this question of standards and of the possibility of adult part-time students attaining a university standard, Mr. Raybould emphasizes one argument for university participation in adult education which has gained much force since it was considered by the Oxford report of 1909 entitled "Oxford and Working-class Education", and that of the Ministry of Reconstruction in 1919. Both reports recognized adult education as a means by which the universities can play a part in equipping men and women in all walks of life for discharging effectively their responsibilities as members of a democratic community. Subsequent political developments have strengthened this argument. As Mr. Sydney Ball remarked in a paper at the Workers' Educational Association Conference at Oxford last year: "Changes in the structure of English Society are throwing more and more responsibility on the shoulders of men who have had no opportunity of obtaining the synoptic mind which, as Plato says, is desirable in governors".

Nor is this all. Mr. Raybould himself adds that the increasing complexity of industrial organization, and the growing tendency of different classes to live in different quarters of the same town, or even in different towns, make it increasingly difficult for the various sections of the community to appreciate each others' circumstances and aspirations. That reason alone would make it important for leaders of every class to have an opportunity of obtaining a wide outlook on the historical development and economic condition of the whole English community, such as can be given by a university education. This point of view was strongly endorsed in the paper on "Some Aspects of Technical Education in the United States and Great Britain" which Dr. P. F. R. Venables delivered at the British Association meeting last August. Noting that the emphasis placed in the United States on general education and social studies in the curricula for courses for technological degrees is primarily on professional grounds, he suggested that this aspect of technological education deserves more attention in Great Britain than it has received. Even for part-time degrees and 'higher national certificates', he suggested that experiment is required in the provision of such post-advanced courses, especially by university extra-mural departments, and that such part-time postgraduate courses would have the advantage of being given to older students with industrial experience of potential significance.

The value of that argument is fully admitted by Mr. Raybould in discussing the question of standards; but Dr. Venables advances a further reason which, particularly at the present time, should ensure that the claims of adult education on the universities receive careful evaluation. Dr. Venables expresses the view that the courses in engineering and business administration described in the United States as 'social technology' have completely justified themselves, both as regards the students and also as regards industry, which because of its increasing complexity and its social problems needs men who are trained to handle people as well as to initiate and develop processes. He suggests that we would do well to examine the possibility of making similar provision in Great Britain, and not least in relation to productivity problems.

Any such examination must at present take account of what is being done both in the universities and in the technical colleges, and emphasizes the undesirability of dealing with technological education and university education in isolation, either from one another or from adult education in general. Mr. Raybould urges almost as strongly as Dr. Venables that not only are industrial relations an important subject of study in universities as well as elsewhere, but also that, because of the concern of such study with ends as well as means, it is particularly appropriate for association with adult education, when theory can illuminate—and itself be illuminated by—practice. Such subjects as international relations and industrial relations are, he suggests, more effectively developed as adult than as undergraduate studies, and in no other subject is there greater need for the characteristic methods and virtues of the university—thoroughness, candour and tolerance.

Persuasively though Mr. Raybould presents these important arguments for university participation in adult education, he does not disguise the test of such participation which he himself suggests. He contends that whatever the subjects studied, the attainment of a 'university standard' of work in extra-mural classes normally demands a long and systematic course of study. Given this and the conditions implied, but not otherwise, Mr. Raybould maintains that adults may, in part-time courses, undertake work and achieve results which justify universities in providing the teaching, particularly in the humanities and in those studies needed for the effective discharge of the responsibilities of citizenship. Since 1945, however, university extra mural agencies have provided a much larger number and proportion of short courses not involving "serious student effort" than at any time before that date. The expectation that the short courses would lead to longer and more systematic courses has not in general been realized. Accordingly, Mr. Raybould suggests that a radical change of policy in extra-mural work is required, with a shifting of emphasis from quantity to quality. First, he would omit most of the short courses which do not involve, in addition to attendance at lectures and discussions, directed study on the part of the students, apart from such courses, such as refresher courses designed to keep graduates engaged in teaching, industry or professional work in touch with current research in their special subjects. In most universities this policy would involve a scaling-down of programmes of work and the transfer of responsibility for elementary courses to other bodies such as the Workers' Educational Association.

Mr. Raybould recognizes clearly what is implied by such a policy, and the modifications in organization, the staffing of extra-mural work and financial arrangements which are involved. These are discussed in successive chapters in which criticisms already advanced of university participation in this work are considered in relation to particular points. All his experience does not make Mr. Raybould dogmatic; but he is confident that the difficulties can be overcome and is convinced that here is work which the universities should undertake, but with deeper insight and a fuller sense of responsibility, and with something of the spiritual impulse which inspired the whole movement thirty or forty years ago. Only then are the universities likely to avoid the danger of dissipation of their resources.

There can be no question that constructive and imaginative thinking is required, no less on the part of the universities than of the Workers' Educational Association itself. To the future policy of that Association Mr. Raybould directed attention in his booklet "The W.E.A.—the Next Phase", published two years ago. The questions there discussed are raised again in his book, and in a wider context, which makes it clear that the right answers can only be found when the functions of the universities and the broad educational situation of Great Britain are taken into account. The vital need is for fresh thought about the nature and purpose of adult education.

'OPOSSUM SHRIMPS'

The British Mysidacea

By the late Prof. W. M. Tattersall and Olive S. Tattersall. (Ray Society, Vol. 136, for the Year 1950.) Pp. viii+460. (London: Bernard Quaritch, Ltd., 1951.) 42s.

WHEN Prof. W. M. Tattersall died in 1943, he had been collecting materials for a monograph on the British Mysidacean Crustacea which was to be published by the Ray Society. In this work he had been assisted by Mrs. Tattersall, herself a competent zoologist, who had prepared a considerable number of the illustrations. Most of the voluminous material, however, was in the form of notes, lists of localities and so forth, and only a few pages were actually ready for the printer. Mrs. Tattersall resolved to undertake the heavy labour of completing the monograph, incorporating her husband's notes and preparing the rest of the drawings. It may be said at once that she has accomplished admirably her self-imposed task, and that the many friends of her late husband will be grateful to her for having provided this worthy memorial to him.

The book opens with a historical summary of the literature on the group, followed by chapters on the general morphology and bionomics. These chapters are quite competently done, although Prof. Tattersall's great experience would, no doubt, have enabled him to supplement them on many points. It would have been interesting, for example, to have had a fuller discussion of the so-called 'luminous organ', from which the genus *Gnathophausia* derives its name. In the systematic part which follows, the keys to families, genera and species seem to be well constructed, although their adequacy could only be tested by using them in the actual determination of specimens. The generic and specific diagnoses are clearly phrased and so arranged that comparison is easy. The figures are admirably clear and, from an artistic point of view, are not unworthy to be placed alongside the work of such masters of crustacean iconography as G. O. Sars and H. J. Hansen.

A valuable feature of the book is the list of localities in British seas given for each species. These lists are taken from Prof. Tattersall's notes, and, in very many cases, were authenticated by his own examination of specimens. Where this could not be done, the names of the authors responsible for the records are given. As in the case of many other groups of marine invertebrates, these lists show how patchy is our knowledge of the distribution of the littoral fauna around British shores. Very few marine laboratories have published lists of the local fauna like that available for Plymouth, and over great stretches of coastline where there are no laboratories the composition of the littoral fauna is a subject for guesswork. For example, there is some reason for believing that the fauna of the shores of the Moray Firth differs considerably from that of the rest of East Scotland; but there are very few Mysidacea recorded from it in this work.

A good deal of importance is attached to Geoffrey Smith's supposed discovery of a vestigial exopod on the mandible of *Paranaspides* (which is not, of course, a Mysidacean, as the unwary reader of p. 10 might be led to suppose). It is necessary, therefore, to say that no one has been able to confirm Smith's statements on this point and that the 'exopod' was certainly absent in the single specimen dissected by the present writer in order to search for it.

Misprints and similar errors, although not numerous, are sufficiently conspicuous to suggest inadequate proof-reading, for which, of course, the author may not be to blame: "neutral" for "neural" makes nonsense on p. 360; Davis Straits is not in Scotland (p. 119), nor St. Andrews in the "north" of that country (p. 372); the maxilla is not a "thoracic" appendage (p. 300); and a very distinguished British zoologist of the last generation (or the one before that, perhaps) did not spell his name "Lancaster" (p. 433). Finally, several references in the text are not explained in the bibliography at the end of the volume.

W. T. Calman

NATURAL HISTORY OF GUANOS

Survey of Existing Knowledge of Biogeochemistry, 3
The Biogeochemistry of Vertebrate Excretion. By George Evelyn Hutchinson. (Bulletin of the American Museum of Natural History, Vol. 96.) Pp. xviii+554+16 plates. (New York: American Museum of Natural History, 1950.) 10 dollars.

GUANO has played a considerable part in agricultural history. The original Peruvian material began to be imported into Great Britain, in substantial amount, during the 'hungry forties' of the nineteenth century, and for more than a generation it constituted a substantial part of the total fertilizer supply. In the southern part of the United States, also, it restored the productivity of the worn-out soils of the old tobacco and cotton plantations. We now know that its effects are to be explained simply enough—it provided both phosphate and nitrogen in concentrated and readily available forms. But farmers often thought of it as something with quite miraculous properties.

Mr. G. E. Hutchinson's monograph is by far the most complete treatise on the subject, and the standard of his scientific scholarship is of the highest. He enumerates and describes the known deposits, analyses the climatological and biological conditions under which they have been formed, critically examines the great mass of literature and points to the lack of proof for some of the earlier theories and to the remaining gaps in our knowledge.

Many of the broad generalizations about guano formation are easily to be understood. Large volumes of excrement and egesta will be deposited wherever large numbers of sizable animals congregate to rest or to rear their young. Marine birds and seals yield the largest quantities of possible raw material; and in both cases a fish diet results in material with high initial contents of phosphates and of nitrogen compounds. But, other things being equal, the product from birds will have the higher value, because the excreted nitrogen is mostly in the relatively stable form of uric acid and, moreover, is in a semi-solid form that is rapidly desiccated. Preservation is tolerably complete only on rainless sites, because even moderate and occasional moistening leads to a breakdown of nitrogen compounds into volatile products. Again, the eggs and young of sea-birds are liable to wholesale destruction by land predators, so that island sites are the only ones that can support large permanent bird-colonies; certain rainless islands, however, are uncolonized because soil or rock surfaces reach day temperatures that are lethal to developing embryos.

In many cases the population of guano birds shows marked cyclical changes—usually a gradual build-up followed by holocaust. The latter does not seem to result from a build-up either of birds of prey or of parasites, and famine rather than epidemic disease seems to be the common cause. The catastrophic falls are more marked among surface-feeders than among deep-diving species, and may thus probably be related to changes in the size and frequency of shoals of shallow-swimming fish. Where the chief food of a particular surface-feeding bird is a species of fish that swims at depths which vary according to the relative temperatures of the upper and lower waters, the immediate cause of catastrophe might be, for example, a persistent high temperature of the uppermost layer of the sea. It is thus tempting to believe that the ultimate cause of the bird's population cycle is to be sought in a regular cyclical change in ocean currents. But catastrophes do not seem to occur with the degree of regularity that would be expected on such a hypothesis.

Mr. Hutchinson's study will be of great interest to students of animal population.

J. A. Scott Watson

THE GORILLA

The Anatomy of the Gorilla

The Studies of Henry Cushier Raven, and Contributions by William B. Atkinson, Herbert Elftman, John Eric Hill, Adolph H. Schultz, William L. Straus, Jr., and S. L. Washburn. Arranged and edited by William King Gregory. (The Henry Cushier Raven Memorial Volume: a Collaborative Work of the American Museum of Natural History and Columbia University.) Pp. viii+259 (116 plates). (New York: Columbia University Press; London: Oxford University Press, 1950.) 97*s.* 6*d.* net.

At the time of his death in 1944, Henry Raven was curator of the Department of Comparative Anatomy of the American Museum of Natural History. He had been a naturalist from boyhood and had visited many parts of the world in search of birds and mammals for the American Museum. In 1929 he returned from an expedition to Africa with a collection of 'pickled' gorillas and also a young live chimpanzee, which soon became a celebrated character in New York. She lived in the Raven house, and took part in a number of Raven's public lectures on anthropoid life. From this time on, his interests became increasingly fixed on the primates, and during the ensuing years he devoted much time to the anatomical study of the gorillas which he had brought back from the jungles of the Belgian Congo and the Cameroons. His death occurred before the completion of his task, and the present volume is a record of his own descriptions of the muscles, blood vessels, peripheral nerves and reproductive organs, supplemented by notes provided by the late J. E. Hill. Raven was primarily interested in regional anatomy, and his descriptions do not attempt to correlate form with function, nor to compare the anatomy of the gorilla with that of man and other primate types. The volume has been rounded-off with short contributions on the thoracic viscera, by S. L. Washburn; on the abdominal viscera and female reproductive system, by H. Elftman and W. B. Atkinson; on the skin, by W. L. Straus; and on the skull, teeth, palatine ridges and growth, by A. H. Schultz.

Raven's detailed descriptions of the musculature of the gorilla are accompanied by a magnificent series of plates and line drawings, many of which were prepared under his personal supervision. Partly, however, because of his premature death, the balance of his section of the volume is uneven. Thus, in contrast to the detail with which he treats the muscles, he devotes only a few pages to the vascular and reproductive systems. The osteology of the gorilla—a subject of great importance in the study of primate fossils—is dealt with scarcely at all. This lack of balance is unfortunately not corrected by the supplementary chapters in the book which, while they also provide excellent and much-needed information, again deal only with limited aspects of the subject.

Dr. W. K. Gregory points out in a foreword that Raven began his dissections of the gorilla with the object of providing a "comprehensive anatomy of this great near relative of man". There can be no doubt that, while he was prevented from doing this, he has nevertheless left what the fly-leaf calls a "permanent definitive work in this field". In the chapter which he has provided, Prof. Schultz remarks that "the literature on gorillas contains many premature generalisations supported by far too few observations". In as highly variable an animal as the gorilla, he goes on to say, "large series of specimens must be investigated in order to establish really representative averages and to find the full ranges of individual variations". The anatomy of the great apes has never been studied, as he indicates, on a scale commensurate with the prominent position these animals occupy in discussions on human evolution. The Raven Memorial Volume helps to show how small is the area of anatomical fact on which these evolutionary discussions are based, and how much needs to be done to strengthen the factual foundation on which has been built so large and detailed a superstructure of phylogenetic speculation.

NEO-VITALISM AND FARMING

Food, Farming and the Future

By Friend Sykes. Pp. 294. (London: Faber and Faber, Ltd., 1951.) 21*s.* net.

Of late years there has been a revival in certain agricultural circles of the old vitalistic ideas formerly widely held until Wöhler's synthesis of urea broke down the distinction between substances which could be prepared in the laboratory and those which could not, but required the intervention of a living organism. Broadly speaking, the position of their successors to-day is that the nutrient salts considered by modern plant physiologists as necessary and sufficient for the full growth of plants are in reality not so, but they need in addition some vital principle which has hitherto eluded chemists and physiologists. In addition to the well-recognized continuity of life through the seed, there is another continuity through the nutrients, and unless these have recently formed part of some living organism the plant, though morphologically complete, lacks some essential quality; in particular, it becomes susceptible to disease, and if fed to animals or human beings induces a like susceptibility in them.

The idea was put forward by the late Sir Albert Howard, and its element of mysticism and supposed naturalness at once made an appeal; it was taken up by a group of able and persuasive advocates of whom Mr. Friend Sykes, the author of the present volume, is one of the best known. He has already written "Humus and the Farmer" and had not intended producing another book on the subject; but his correspondence showed that further clarification was necessary, and this he has set out to effect.

Mr. Sykes's farming system consists in growing a four-year ley which, as in the Clifton Park system, includes some deep-rooting plants, and then ploughing up and growing cereals for four years. The straw is converted into farmyard manure in the old-fashioned way by wintering cattle in stock yards, and the manure thus produced is given to the potatoes, kale and other crops. There are no special features here; similar systems can be found elsewhere.

The difference from ordinary farming is that Mr. Sykes uses no fertilizers and no chemical agents for plant or animal protection. By withholding fertilizers he claims that his crops are entirely free from disease and produce seed free from adherent fungus spores, so that no seed dressing is ever required; that his animals likewise suffer neither disease nor sterility; and further, that his cereals have a health-giving quality lacking in ordinary farm produce. He recognizes that the basis of his crop production is the nitrogen of the air as in ordinary farming, but he maintains that the plant nutrient produced by microbiological fixation has far greater value than that produced by catalytic fixation; the end-product is nitrate, but in one case the nitrate is natural and associated with the vital principle, and in the other it is artificial and devitalized.

Unfortunately, the evidence for the claim is entirely subjective. Mr. Sykes claims to be able to detect by taste the difference between humus-grown crops and those produced in the usual way. An experiment on the farm scale has been set up; it will be convincing only if both design and execution conform to modern standards. In these days of hormones, trace elements and isotopes, no responsible scientific worker would pretend that the full story of plant nutrition is yet known; but standards of experimental technique have advanced greatly in recent years, thanks largely to the Rothamsted workers, and experiments can be designed in such a way that the validity of the results can be tested. Only when satisfactory evidence can be adduced are the theories of the author's group likely to be accepted. E. John Russell

LEEUWENHOEK

Antoni van Leeuwenhoek

Zijn Leven en zijn Werken. Door Dr. A. Schierbeek. Deel 1. Pp. 278+18 plates. 10 f. Deel 2. Pp. 281–526+10 plates. 12 f.
(Lochem: 'De Tijdstroom', 1950–51.)

THE literature that has rapidly grown up around Leeuwenhoek since the publication of Dobell's classic work in 1932 would suggest the preparation of a general treatise devoted to his scientific researches as a whole. Dobell's study, admirable as it is, covers only a small fraction of the work of the celebrated Hollander. Out of a projected total of twenty volumes of the "Opera Omnia" the Leeuwenhoek Commission of Amsterdam has so far produced only three volumes since 1939, and the War has well-nigh shelved this sumptuous and costly enterprise. If, however, as we all hope, it can be completed on the scale of the detailed magnificence of the early volumes, we shall have a monument to Leeuwenhoek worthy of the man and of the Dutch nation. The recently instituted Leeuwenhoek lecture by the Royal Society is not intended to deal with Leeuwenhoek's own work, but rather with *modern* developments in microbiology—a branch of science in which Leeuwenhoek's discoveries have earned for him the title of 'Father'.

Dr. A. Schierbeek's book, therefore, comes at a time when an inclusive and critical examination of Leeuwenhoek's researches based on a thorough knowledge of all the original letters in Dutch, and also on the labours of modern commentators, might reasonably have been expected. It is true that such an author would find his own knowledge of biology severely tested, and, moreover, several minor researches of his own would be necessary before a final judgment could be reached on those points which always emerge during the progress of such a work. Dr. Schierbeek's professional duties are sufficiently exacting to tax both energy and endurance, and he is to be congratulated on the production of a learned work which must have entailed considerable literary and objective research. Its wide scope and complexity is indicated by the following translation of the chapter and sectional headings, outlining Leeuwenhoek's personality and researches, into which the text is divided. Vol. 1. (1) Life and works. The first forty years. As a citizen, an usher in the council chamber, a wine gauger, surveyor, and an amateur scientific worker. His mentality and psychological type. (2) His microscopes and research methods. (3) His attitude towards inorganic Nature and concern with mathematics, physics, chemistry and geology. (4) As the father of microbiology. On free-living and parasitic unicellular animals, rotifers, phytoflagellates, soil micro-organisms, seaweeds, mildew, bacteria and yeast. (5) On the study of the lower animals, such as stinging animals (Cœlenterates), sponges, molluscs, worms, spiders, and the higher Crustacea. (6) As an entomologist. On the anatomy of advantageous instincts, compound eye, galls and gall insects, clothes [body] louse, flea, grain weevil and its treatment, aphis, parthenogenesis and ichneumon parasites. The first volume closes with a genealogical table of the Leeuwenhoek family.

Vol. 2. (7) On the investigation of the vertebrate animals. (8) Discovery of the spermatozoa and views on generation. (9) As an histologist. On the structure of muscle, blood corpuscles and blood vessels, digestion and microscopic structure of gut, bone, teeth, skin, sweat glands, hair, nails, structure of nerves, brain and spinal cord, lens of eye, tongue, saliva, nasal mucus, phlegm, ear, kidney, bile production, milk, fat, ciliated epithelium, chromatophores, and nuclei. (10) Medical observations. (11) On botany. Structure of wood, structure of monocotyledons, tyloses, vessels, vacuolated tissue, raphides, starch, movements of sap, fruit and seed, growth of meristem in wheat ear, laticiferous vessels, stinging hairs, hairs of Labiatæ, and plants used in medicine. (12) As ecologist. (13) Summary and appendixes. The published letters and bibliography of Dutch and Latin editions. The relevant literature.

Dr. Schierbeek surveys this comprehensive and bewildering field with the confidence of an enthusiast steeped in his subject, and, as a Dutchman, better able to unravel Leeuwenhoek's many puzzling and involved passages, often made less intelligible by his use of obsolete colloquialisms. I regret the mistake of publishing so important a work in a language unfamiliar to the larger foreign public attracted by the subject. Perhaps Dr. Schierbeek will now prepare an English translation, for which a publisher could readily be found in Britain, if not in Holland. In framing the idiom of the Dutch text of his work, I fear that Dr. Schierbeek has not always borne in mind that the affairs and work of Leeuwenhoek interest a widening non-Batavian circle.

[Since the above notice was written, Dr. Schierbeek has been approached by an American publisher with an offer for the publication of an English translation of his memoir.] F. J. Cole

The Middle East

A Physical, Social and Regional Geography. By Dr. W. B. Fisher. Pp. xiii+514. (London: Methuen and Co., Ltd.; New York: E. P. Dutton and Co., Inc., 1950.) 27*s.* 6*d.* net.

THE first problem with which Dr. W. B. Fisher had to contend was the definition of the Middle East, a term that is used in widely varying senses. He regards as a unit the area east from Cyrenaica, Crete and Egypt to Arabia and Iran and north to Turkey. No other part of Africa is included. His use of the term leaves no room for the cognate one of Near East, which is generally applied to the eastern end of the Mediterranean. But, after all, this is only a matter of nomenclature and does not affect the value of the book. The physical background outlined by Dr. Fisher is relatively slight but adequate, and his treatment of the climate and vegetation is specially good. But interest on the whole is concentrated on the social, economic and historical aspects. The book is readable and none too long for the vast scope of its subject. In places it is unduly brief, for example, on the Suez Canal in both its physical and political aspects and perhaps also on Egypt. There are many sketch maps, some a little crude, and adequate bibliographies. R. N. R. B.

Land Utilization in Australia

By Prof. O. M. Wadham and Prof. G. L. Wood. Second edition, revised. Pp. xx+376+77 plates. (Melbourne: Melbourne University Press; London: Cambridge University Press, 1950.) 30*s.* net.

THIS post-war revision of a valuable study will be read with interest by those concerned with the land resources of the world and their utilization. The special interest of this edition is twofold. There is a consideration of the impact of war-time production and trade in the Australian Continent and the influence of such factors as the closing of markets, new needs, such as the British demand for flax, and even the American soldier's non-acceptance of mutton. Then there is the assessment of the question of post-war development and the discussion of settlement possibilities, always a matter of interest so far as Australia is concerned. Here the exposition of the deterrents to any close settlement of even the more favoured regions is of particular note and should be studied by those who tend to take a facile view of migration as a cure for world population problems. The authors can scarcely be blamed for the present-day difficulties, which impose a time-lag on publication and which thus make some of the statistics seem a bit out of date and prevent any consideration of the influence of recent changes in the price of wool.

Bibliography of Electron Microscopy

Edited by Dr. V. E. Cosslett for the Institute of Physics. Pp. 350. (London: Edward Arnold and Co., 1950.) 40*s.* net.

THE electron microscope as a research tool is now about ten years old. During that period there has grown up an abundant literature, dealing with basic electron optical theory, with the production and interpretation of electron micrograms, with techniques for preparing specimens to meet the exacting requirements of the instrument and, latterly in particular, with its applications in many different branches of science and technology. Dr. V. E. Cosslett and his team have done an excellent job in preparing this comprehensive bibliography, which covers some 2,500 papers published up to the end of 1948. The field covered appears by test to be well-nigh complete, and abstracts are given of the majority of the papers included.

It is a pity, however, that the material has been arranged only in alphabetical sequence of authors. One would have thought that it would not have involved undue additional labour to have added a subject guide, or preferably to have arranged the items primarily by subject, with an alphabetical author index—a task which would have been greatly helped by numbering all the items in a single sequence. The very breadth of the subject-matter makes the lack of some such arrangement all the more regrettable, and it is to be hoped that any future volume will be improved in this respect. L. V. CHILTON

Organic Syntheses

An Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. Vol. 30, 1950. Arthur C. Cope, Editor-in-Chief. Pp. vi+115. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1950.) 20*s.* net.

THE thirty-nine preparations described in this volume offer, as usual in this admirable series, a wide variety of substances and methods. The formation of *trans*-2-chloro*cyclo*pentanol from *cyclo*pentene is an interesting example of the use of monochlorourea, prepared from urea, as a source of hypochlorous acid. An attractive synthesis of ethanedithiol proceeds from thiourea and ethylene dibromide via ethylene-di*iso*thiuronium bromide. Dihydropyran, obtainable by dehydrating tetrahydrofurfuryl alcohol, furnishes glutaric acid in excellent yield through hydrolysis and oxidation with nitric acid. The preparation of *cis*-Δ^4-tetrahydrophthalic anhydride by the addition of butadiene to maleic anhydride is described with a useful diagram of the apparatus furnishing a yield of 93–97 per cent. Among other preparations are fumaronitrile, methanesulphonyl chloride, 1-naphthaldehyde, phenylacetylene, *o*-tolualdehyde, vanillic acid and the vinyl esters of a series of the higher fatty acids.

JOHN READ

Tropical Fishes as Pets

By Christopher W. Coates. Reprint. Pp. xi+226+29 plates. (London: Jonathan Cape, Ltd., 1951.) 12*s.* 6*d.* net.

THIS book has a much wider market than when it was first published seventeen years ago. For in that interval the number of people who keep tropical fish for pleasure or profit has increased enormously. Mr. C. W. Coates, who is a specialist in tropical fish at the New York Aquarium, gives good descriptions of most of the exotic fishes likely to be available to British aquarists.

After stressing that nobody should attempt to keep fish unless possessed of something called 'fish sense', he also provides four informative chapters on fish management. It is an unfortunate fact that the length of the technical names of these fishes seems to be inversely proportional to their body-length. Also Mr. Coates does not help matters for the lay reader by using the full scientific names; thus *Platypoecilus maculatus* is surely long enough for a one-inch fish without making it *Platypoecilus maculatus* Guenther.

The fifty-seven photographs are a mixed lot. A few are good, but too many are so dark that the fishes can barely be distinguished.

UNDULATORY PROPULSION IN SMALL ORGANISMS

By Prof. J. GRAY, F.R.S.
Department of Zoology, University of Cambridge

DURING a recent discussion[1] on the movements of bacteria, two main theories were advanced: first, that movement is due to the active undulations of numerous fine flagella, projecting from the surface of the cell and seen as fine wavy, but disorientated, filaments when the dead cell is examined under the electron microscope; and secondly, that propulsion is due to undulations of the whole cell, the so-called 'flagella' representing material sloughed off from the cell surface to form a twisted inactive tail. The object of the present communication is to consider these two theories in the light of four principles which have emerged from a study of other types of undulatory propulsion.

(1) From a mechanical point of view, there is no fundamental difference between an undulatory change in form by the whole cell and a similar change exhibited by a filamentous flagellum. All two-dimensional undulatory movements—irrespective of the size and internal structure of the organisms concerned—are expressions of two essential facts: first, that every part of the system is, by internal effort, bending alternately towards its 'right' and 'left' side; secondly, that the phase of the bending cycle exhibited by any unit length of the system is slightly ahead of that of the unit length lying immediately behind, but is slightly behind that of the unit situated immediately in front; in other words, the curvature at any region of the body is constantly changing towards that characteristic of the immediately anterior region, thus causing the wave to travel from 'head' to 'tail'. The form of the wave depends on two factors: the radius of curvature of a unit when bent to its maximum extent and the difference in curvature between successive unit lengths of the body, that is, on the difference in phase of bending per unit length. In order to execute these co-ordinated bending movements each unit length must possess: (i) tensile elements capable of shortening in length and of developing tension against the internal and external forces which oppose the process of bending; (ii) compression elements (equivalent in function to the vertebral column of an eel) which enable the energy of the tensile elements to be expended in the form of bending couples; (iii) a mechanism which controls the phase difference between adjacent lengths of the undulating system.

(2) Forward motion of the whole organism—whether it be a snake or a spermatozoon—occurs when the organism exerts its bending movements against external environmental resistance acting normally to the surface of the body.

Fig. 1*a* shows the general distribution of external forces acting against the body of an undulating organism. The forces (*R*) acting normally to the surface of the body are equal but opposite to the frictional forces (*F*) acting tangentially to the surface. Fig. 1*b* shows the relationship of the external forces acting against a single wave to the activity of the internal contractile elements. In the leading half of the wave *AB*, the contractile elements of the right side are shortening progressively from *A* to *B* and the body is thereby braced against the external resistances S_1, S_2 and S_3. The reactions R_1, R_2 and R_3 yield a resultant P_1 equal but opposite to F_1, F_1. Between *C* and *A* the contractile elements of the left side are shortening and the body is braced against S_4, S_5 and S_6, thus yielding a propulsive force P_2 equal but opposite to F_2, F_2. When the two half-waves operate together, the reactions from S_3 and S_4 are equal but opposite, and constitute transverse shearing forces at *A*.

Hence it can be shown that the forward propulsive thrust is proportional to the rate of change of curvature along the body and to the total length of the body; in other words, it is dependent on the form and speed of the waves.

(3) Effective propulsion in water only occurs when the body is long enough to exhibit at least one complete wave of sufficient amplitude, and since the form of the wave can be controlled experimentally by varying the physical condition of the medium the form can be changed to such an extent that the animal can no longer progress. This is particularly obvious in the case of short nematodes such as *Hæmonchus* or *Anchylostoma*, which creep with great efficiency through a relatively rigid medium such as agar. When placed in water the amplitude and wavelength of the undulation are increased to such an extent that the animal fails to form a complete wavelength along its body; under these conditions the animal does not progress, although it continues to display rhythmical undulations. The forms of these nematodes when in water are very similar to those of the bacteria in Pijper's photographs. (A detailed analysis of the movements of flagellated organisms

Fig. 1

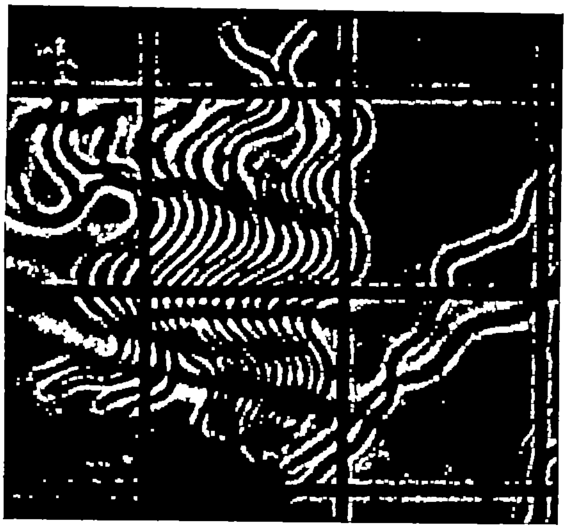

Fig. 1. Photograph of a group of living *Cristispira balbianii* showing synchronized movements in a thin film of water. The anterior ends of the organisms are attached to a glass slide. The sides of the black grid are 40 μ

in water is a formidable mathematical problem which is at present being examined by Sir Geoffrey Taylor.)

The sensitivity of wave form to external mechanical forces is a very widespread phenomenon among undulatory animals. A somewhat specialized but interesting example is shown in Fig. 2, which demonstrates the co-ordinated activity ensuing when two or more active organisms are sufficiently close together to exert mechanical forces on each other. These and other facts suggest that the difference in phase between adjacent regions of an active flagellum is controlled by the external physical forces acting against its surface.

(4) When a large animal (for example, an eel) is undulating in water, some of the energy required to bend the distal regions of the body and to drive these through the water are transmitted (by the body's own elasticity) from other regions lying nearer the head of the animal. In a flagellum, perhaps 0·5 μ in diameter, moving at 100 μ per second, the amount of energy which can be transmitted in this way is negligibly small compared with that required to move the flagellum against the viscous resistance of the water. Each short unit length of the flagellum must provide the whole of the energy necessary to maintain its own motion.

An application of these four principles to bacterial propulsion leads to the conclusion that the length of a bacterium and the ratio of amplitude to wave-length of its bodily undulations are both too small to sustain an efficient propulsive thrust. On the other hand, if the whole surface of the body were covered by an active sheet able to undulate with the wave-length and amplitude of the 'tails' shown in Pijper's figures, the organism would progress, and if some of this sheet were 'sloughed off' behind the organism, the 'tails' described by Pijper might well result. If the frequency of undulation were of the same order as that of the tail of the spermatozoon of a sea urchin, the waves would only be visible under stroboscopic darkground illumination. A post-mortem degradation of such an active sheet into a series of disoriented fibrillar elements would be in accordance with the behaviour of a wide variety of vibratile structures, and may explain the apparent existence of discrete flagella in electron micrographs of bacteria.

It is difficult to believe that disorientated fibrils such as those revealed by the electron microscope could propel a bacterium unless, during life, the fibrils are orientated in an antero-posterior direction. On the other hand, a series of active flagella in close proximity to each other would most probably develop synchronized movements. It would be very difficult to distinguish a true membranous sheath from a series of parallel filaments if both were propagating waves of identical form and frequency. From this point of view there seems little difference between the two theories.

A note of caution may perhaps be sounded concerning the functional interpretation of the fibrils and other structures revealed by methods which involve the destruction of the flagellum as an active dynamic system. The X-ray diffraction patterns of these fibrils suggest that their molecular structure is not dissimilar to that of hair and other natural fibres. The central problem is to endow such a system with three essentially dynamic properties: (1) the generation of internal bending couples; (2) the maintenance of phase difference in dynamical activity along the fibril; (3) the generation of free mechanical energy along the whole length of the fibril. To provide a picture of intra- or inter-molecular forces capable of meeting these requirements would be a major contribution to biology: at present, it is only possible to speculate how far internal bending couples could be generated within a long fibrillar molecule by a redistribution of intramolecular groupings of the type postulated by Meyer and Mark[2] and others for muscular contraction, the function of the vertebral column of the eel being performed by mutually repellent charges and that of the muscles by attractive charges. Such a system, if sensitive to mechanical stretch, would at least have some of the properties of an active flagellum, although there would still remain the necessity for periodic changes in the distribution of the charges concerned.

GEORGE FRANCIS FITZGERALD, 1851-1901

CENTENARY MEETING AT THE ROYAL DUBLIN SOCIETY

G. F. FITZGERALD is unique in the history of modern science in that the fundamental hypothesis for which he is most remembered is one upon which he himself published nothing. This is the hypothesis that a moving body is contracted in the direction of its motion. Its historical significance can scarcely be over-estimated. For it asserts that the length assigned by an observer to a rigid body depends not only upon the body but also upon its relationship to the observer. It was therefore an attack upon the whole classical concept of space, according to which space possesses a geometry identical with that of a classical rigid body, the latter being supposed the same for all observers. FitzGerald's suggestion was the first of those which led to the emergence of 'post-classical' physics.

FitzGerald's priority in this matter has never been questioned. As is well known, he made the suggestion in order to account for the null result of the Michelson–Morley experiment. Sir Oliver Lodge has told[1] how he had it from FitzGerald in 1892; H. A. Lorentz made the suggestion independently shortly afterwards, but then acknowledged FitzGerald's priority.

FitzGerald was born on August 3, 1851, the son of William FitzGerald, afterwards Bishop of Cork and later of Killaloe. His mother's brother was George Johnstone Stoney, who also anticipated a fundamental concept of modern physics, the electron, and to whom is due the current use of the term. As boys, FitzGerald and his brothers were educated at home, one of their teachers being a sister of George Boole. FitzGerald entered Trinity College, Dublin, in 1867, became a Fellow in 1877 and Erasmus Smith professor of natural and experimental philosophy in 1881. These appointments he held until his death in 1901, at the age of forty-nine.

FitzGerald was one of the prominent figures in late nineteenth century science. He is noted for a great deal more than the one hypothesis already mentioned; in fact, he is one of the most frequently quoted authors in Sir Edmund Whittaker's "History of the Theories of the Aether and Electricity" (second edition, Edinburgh, 1951). As early as 1883 he showed theoretically[2] that electromagnetic waves "of as little as 10m. wavelength or less" could be generated by oscillating electric circuits; and it is interesting to recall that in 1898 he took part in Marconi's demonstration in Dublin Bay of ship-to-shore wireless transmission which resulted in the first newspaper publication (in the Dublin *Evening Mail*) of news obtained by wireless. In 1888 he anticipated theoretically the modern use of the coaxial cable and wave-guides[3]. These are examples of his gift for throwing out brilliant suggestions which were much in advance of his time and which he himself did not pursue very far. Indeed, Oliver Heaviside wrote, "He had, undoubtedly, the quickest and most original brain of anybody. . . . He saw too many openings. His brain was too fertile and inventive. I think it would have been better for him if he had been a little stupid—I mean not so quick and versatile, but more plodding. He would have been better appreciated, save by a few." But his brilliance and versatility operated against the development of his own work also by laying him open to unceasing consultation by others, and he perhaps erred on the side of generosity in the help he gave. In addition, he played an influential part in the furtherance of university and technical education in Ireland.

A large proportion of FitzGerald's papers appeared in the *Proceedings of the Royal Dublin Society*, and he was from 1881 until 1889 honorary secretary of that body. On October 30, 1951, the Society devoted one of its scientific meetings to the celebration of the centenary of his birth. The chair was taken by the president, Major A. McMorrough Kavanagh, and afterwards by Dr. A. Went (committee-chairman). There were present one of FitzGerald's sons, Sir Raymond FitzGerald, a daughter, Mrs. Scott, and other relatives. The Physical Society of London, of which FitzGerald had been president in 1892, was represented by Prof. K. G. Emeléus. Messages were received from the Institution of Electrical Engineers, of the Irish Section of which FitzGerald was the first chairman (1899), from Sir Edmund Whittaker and from Dr. G. F. C. Searle, who had known him personally. The Provost of Trinity College, Dublin, Dr. E. H. Alton, gave personal reminiscences of FitzGerald, and quoted tributes to his character as a man in which his contemporaries had dwelt especially upon his complete freedom from considerations of his own self-interest. Dr. Alton also showed photographs[4], taken by J. Joly, of FitzGerald's pioneering experiments in human flight in a glider constructed by O. Lilienthal in Germany. Prof. F. E. W. Hackett (University College, Dublin) spoke of 'FitzGerald as revealed by his letters to Heaviside". Photostat copies of the letters, presented by the Royal Institution, were on view at the meeting. Since the exchange of views between the two men depended almost entirely upon their correspondence, these letters give much insight into the working of FitzGerald's mind. They are enlivened by that sparkle which, according to Praeger and Lodge, characterized his talk at a lunch-table or at a scientific discussion.

The main theme of the meeting was, however, the significance of the FitzGerald–Lorentz contraction. The noteworthy feature was the demonstration that this is still a live subject, the papers contributed being far from mere historical reviews. For it cannot be denied that there is at the present time a widespread reaction against the theory of *general* relativity on account of the difficulty of applying it to problems of interest, the still greater difficulty of knowing what the theory really signifies, and the lack of success of 'unified field-theories'. This situation itself was not discussed. It is mentioned here because it is resulting in the realization that there is still important fundamental work to be done in the *special* theory of relativity (using this term without reference to any one particular formulation of the theory) which is free from the objections to the general theory. The papers read at the meeting can be regarded as part of the outcome of the situation.

The chief address was by Dr. Herbert E. Ives (New York). He started his comprehensive and critical historical review with a precise statement of the relation of FitzGerald's hypothesis to the Michelson–Morley experiment. He recalled how FitzGerald's contemporary, Sir Joseph Larmor, had accepted the hypothesis and had remarked in 1900 that it required as a consequence the phenomenon of 'time-dilatation'. Dr. Ives emphasized the really fundamental step which FitzGerald made in compelling us to take explicit account of the behaviour of measuring instruments and also to scrutinize the language employed, which had been developed on the assumption of invariant instruments. Thus he saw in FitzGerald's hypothesis "the germs of what are now called 'the operational principle' and 'semantics' ".

Dr. Ives proceeded to an account of the work of H. A. Lorentz and Henri Poincaré. Lorentz endeavoured to extend to all electrodynamic phenomena the invariance with motion found in the Michelson–Morley experiment. Seeking a principle that would comprehend all the particular ideas of Lorentz, Poincaré formulated[5] in 1904 "the principle of relativity, according to which the laws of physical phenomena should be the same, whether to an observer fixed, or for an observer carried along in a uniform motion of translation, so that we have not and could not have any means of discovering whether or not we are carried along in such a motion". Poincaré then gave the Lorentz transformation in the form in which it is known to-day, though this was a modification of Lorentz's original form.

Dr. Ives then described his own[6] 'operational' derivation of this transformation, assuming only Poincaré's relativity-principle and the accepted result that the velocity of light is independent of the velocity of its source. In terms of his operationally defined quantities, the equations are complicated. "This is the price we have to pay," he said, "for equations which tell a complete and unambiguous story in symbols all of which have a definite operational meaning." However, a change of variables does, in fact, yield the standard form of the Lorentz transformation. One takes it that this substitution provides an explicit operational representation of the clock-synchronization, etc., required, but less carefully examined in more familiar treatments. Dr. Ives went on to a careful inspection of the "principle of the constancy of the velocity of light" which, as usually understood, he rejects.

He described also his well-known experimental verification[7] of the time-dilatation using the spectra of canal rays, following a suggestion originally made by J. Stark[8] and employing A. J. Dempster's method of accelerating canal-ray particles.

Dr. G. J. Whitrow (Imperial College of Science and Technology, London) contributed a paper on "The FitzGerald–Lorentz Contraction Phenomenon and the Theories of the Relativity of Galilean Frames". In the author's absence, it was described by Prof. W. H. McCrea. Dr. Whitrow started by quoting Bishop Berkeley's criticism of Newton's introduction of absolute motion into natural philosophy. The dilemma of Newtonian physics was that, while it held good for all Galilean frames in uniform relative motion, the phenomena of rotation seemed to demand an absolute standard of rest. In nineteenth-century physics this was provided by postulating the luminiferous æther. But the Michelson–Morley experiment demonstrated the impossibility of measuring linear motion through the æther. Einstein's formulation of the theory of special relativity again replaced the æther by empty space, but again gave no explanation of rotational phenomena. E. A. Milne's theory of kinematic relativity and world-structure offered a solution of the difficulty. In his view, the whole system of galaxies, or rather the substratum which in the theory represents the smoothed-out system of galaxies, provides at every point of space an absolute standard of rest and non-rotation. But the theory[9] is complicated by a distinction between fundamental and subsidiary Galilean frames. Dr. Whitrow now proposes a modification of Milne's work which restores to it the formalism of special relativity. The consequence of the work of Milne and Whitrow is thus to provide special relativity with a cosmological background. Dr. Whitrow also related the problem to a view of the philosophy of science which he has recently developed[10].

A paper by Prof. W. H. McCrea (Royal Holloway College, University of London) on "The FitzGerald–Lorentz Contraction—some Paradoxes and their Resolution" dealt with the problem of the rigid rod in special relativity theory. According to the theory, the contraction denotes no intrinsic physical change in a moving rod. Nevertheless, an observer can 'trap' the rod in the contracted state and exhibit it as having undergone such a change. If we define a rigid rod as one through which an impulse can travel with maximum permitted speed (that is, the speed of light), then it becomes clear how such a physical change is produced in the process of stopping the rod. If it is stopped at the forward end, then the shortest length momentarily attained is, in fact, less than that given by the FitzGerald factor. It can be shown that the kinetic energy just suffices to supply the energy of compression without dissipation; consequently the 'rigid' rod can be regarded as being also perfectly elastic.

Prof. J. L. Synge (Dublin Institute for Advanced Studies), in his paper on "Effects of Acceleration in the Michelson–Morley Experiment", dealt also, but more generally, with the rigid-body problem. The definition he gave was in a form due to his pupil, Mr. G. H. F. Gardner, and is based upon the concept of a 'drag-point' in the body, together with a condition requiring that any particle of the body responds to the behaviour of the drag-point only with a delay corresponding to the time of travel of light from the point to the particle. This appears to reduce to McCrea's definition in the case of a one-dimensional body. The definition enables one to study the motion of a rigid body in accelerated motion relative to a Galilean frame. As Prof. Synge pointed out, the Michelson–Morley experiment is one upon the behaviour of such a body, the instrument being in accelerated motion on account of the rotation and revolution of the earth. He stated that Gardner's hypothesis predicts a null result for the Michelson–Morley experiment if the interferometer is loosely attached to the earth, as it appears to have been in the latest repetitions of the experiment which have, in fact, given the null result. On the other hand, if the instrument is rigidly attached to the earth, then the hypothesis predicts a definite result about three times that reported by Dayton C. Miller in his particular repetition of the experiment[11]. The provisional interpretation is that Miller's interferometer had sufficient rigid connexion with the earth to show part of the acceleration effect predicted by the new theory. But, as Prof. Synge took care to state, judgment must be suspended until the theory is tested by specially designed experiments.

All these papers will be published in a special number of the *Proceedings of the Royal Dublin Society*, and will be found to contain much more information than there has been space even to mention in this report.

RABBIT CONTROL IN AUSTRALIA : PROBLEMS AND POSSIBILITIES

THE story of the rabbit in Australia is so well known, so familiar an instance of the spread of an innocent introduction to plague dimensions, that fresh turns in its course must be spectacular to become news. For most of the world beyond Australia, there is the pest, and there are the problems of its control. Even in Australia itself, there has been perhaps a sense of inevitability that this prolific competitor for grazing must embarrass agricultural production, impede attempts to raise both old-occupied and new land to higher levels of fertility and output, and, in fact, place a heavy burden on farmer and pastoralist to exercise control measures. But there is no complacency among the occupiers of land in Australia; in many areas the rabbit-proof fence has become almost as typical a part of the Australian scene as is the gumtree or the Merino sheep, while in Western Australia the 'rabbit-proof fences', State-erected, State-maintained, and State-patrolled, stretch hundreds of miles across the continent to appear, like the Great Wall of China, a monument to the efforts made to stem the invader.

Always the pest has proved highly resistant to any attempts to confine it to limits of area in which it could be effectively tackled by such techniques as digging out warrens, gassing or poisoning, chasing by dogs and trapping, or even to restrict its numbers by such means. The general problem of its control is so severely practical that until about the late 1920's the possibility of scientific aid appeared almost as remote as that of complete eradication of the pest population. The recognition that the virus disease, myxomatosis, might be an agent in reducing rabbit numbers directly invoked scientific inquiry, and although early investigations carried out by the Division of Animal Health and Production, of the then Council for Scientific and Industrial Research, established that the disease could work, its effectiveness was small because of its very limited powers of spreading naturally through rabbit populations and groups. What did emerge, however, was that the problem, scientifically, had to be regarded as a whole, and that the rabbit and its context were fit material for comprehensive biological study.

During the Second World War and its aftermath, difficulties of labour and increasing costs of material for control measures, among others, gave rise to conditions favouring the rabbit. Also, increasing recognition of the importance of ecological and other biological approaches to such field problems ripened the opportunities for long-term research and encouraged the Commonwealth Scientific and Industrial Research Organization to include review of the rabbit problem in the programme of its Wildlife Section, established in 1949, without at the same time offering any optimism of revolutionary systems of control. The Organization has now issued "The Rabbit Problem—a Survey of Research Needs and Possibilities"*, in which F. N. Ratcliffe, officer-in-charge of the Section, assesses the scope for the different control methods, and presents a valuable, critical appraisement of the complex position to be studied.

In broad terms, Ratcliffe distinguishes qualitative differences in the problem, in three categories of country: "(*a*) the relatively low-value, low-rainfall grazing country (typified in N.S.W. by the Western Division); (*b*) the region of high-value grazing country (sheep to an acre or better, down to, say, one sheep to two acres); and (*c*) the closely settled farming areas". In the first, real control is impracticable, mitigation is possible, but serious infestations are limited by adverse climatic conditions; in the last, good farming practice usually keeps the rabbit under control. In the better pastoral country, which includes much of the land amenable to pasture improvement and the wheat areas, the rabbit problem is most acute and most severe economically, not so much from the direct damage as from the tremendous burden, in labour and expenditure, of measures to curb infestation from attaining catastrophic proportions; here, the real need is "for ways and means of bridging the gap between partial control and eradication".

Attempts to use pathogenic micro-organisms in the control of mammal pests have not generally been promising, but there were indications that the use of myxomatosis might give a cheaper method than others of checking rabbit numbers *in the higher-value country*; accordingly, trials were begun to introduce the virus into warrens in this category of land. But the first attempts failed to induce an effective spread of infection.

The survey records the position of other control methods in use, of which fumigation is probably now the most important. Gas is either blown through a burrow system, or is laid to form a zone of lethal concentration at the burrow mouth; carbon monoxide, 'Cyanogas' and carbon disulphide are used for blowing, 'Cyanogas' and chloropicrin are used as barrier zone fumigants. Neither method gives 100 per cent kill owing to the difficult natural conditions under which the fumigants are called upon to operate in the burrows; the choice of compounds possible for use is small, and the only hope appears to be improvement of the standard materials, especially chloropicrin. No effective 'persistent' fumigant has so far been found. Mechanical treatment of warrens by digging out formed a major control method in better-class country, and is now largely superseded by tractor ripping; while this loses effectiveness on stony or hilly land and among tree roots, its potential contribution to control is high when used as part of a planned campaign. Poisoning can kill large numbers of the pest, and its most effective use in reducing infestations is achieved by specialists who have accurate knowledge of the ecology of rabbit populations. The idea of using lures to poisoned baits is popularly attractive, but the evidence is that their effectiveness depends upon prevailing conditions rather than on any special attributes of the odour employed. "Of all the methods of rabbit destruction available, poisoning stands most in need of scientific study and clarification."

No particular promising line of inquiry which might lead to revolutionary new control methods emerges from the survey. There are possible minor improvements in fumigants and fumigation; probable major developments in efficiency of poisoning, but only after prolonged investigations; and a clear need for detailed ecological studies, on the results of which a sound national policy can be planned and put into effect. The report concludes by proposing a scheme for an "experimental area-control campaign," to determine the conditions under which the various control methods can best be integrated to meet local expressions of the problem; for example, to elucidate the conditions under which the target of local eradication must be replaced by that of mitigation and control. But in any such campaign, experimental or as a widely applied policy, the provision of rabbit-proof netting is seen to be essential to separate the areas in which eradication is practicable from those in which it is not.

Thus this report. But as it was prepared, a spectacular development occurred in the development of myxomatosis epidemics. It was known that the disease could be spread from sick to healthy rabbits by certain mosquitoes. As mentioned above, the first attempts to establish the disease in experimental sites were unsuccessful, but by continuing the introduction into warren colonies in the Murray River valley into the summer months of 1950–51, conditions favourable to success were encountered and mosquitoes rapidly spread the disease, so that by February 1951 the disease was reported widely in the Murray River system and its incidence had extended northwards along the Murrumbidgee, the Lachlan, and the Darling Rivers, almost up to the Queensland border, but with a slower spread south of the Murray.

---

* The Rabbit Problem: a Survey of Research Needs and Possibilities. Pp. 17. (Melbourne: Commonwealth Scientific and Industrial Research Organization, 1951.)

Most effective transmission and high rabbit mortality were largely restricted to narrow zones of river frontages and to swampy areas where the dusk-biting *Culex annulirostris* was prevalent; but it was soon evident that 'jumps' of infestation were attributable to the day-biting *Aedes*, which are more widely distributed over open country. Local recessions of the epidemic occurred as the autumn season advanced. The Commonwealth Scientific and Industrial Research Organization had issued recommendations to graziers as to how to set up fresh loci of infection by moving infected rabbits; but by June it had announced that the first great epidemic had passed, leaving a probable toll of millions of rabbits killed and a vast saving of expenditure on control measures and of valuable fodder, over an area "about half the size of the continent of Europe". While the mosquitoes had been the main agents in spreading the epidemic, it was soon recognized that the small black fly *Simulium* was also involved and, later, that the smaller 'true' sandflies are important carriers, especially in parts of Queensland.

Extraordinary local differences in infestation occurred, but there is little doubt that the general direction and vastness of spread were affected by the unusual distribution of conditions that had obtained. Many parts of Victoria had suffered from drought, and there was little spread of the disease south of the Murray valley; to the north, the season had been wetter and wetter, and in parts of northern New South Wales and Queensland the widths of the effective killing zones had become greater, to give almost a general epidemic. The region in which the disease had its most profound effects, namely, those areas west of the foothills of the dividing range watered by the upper tributaries of the Darling River, had experienced some of its worst flooding on record.

Obviously, many questions remain for scientific workers and graziers to answer regarding the potentialities of the disease as an agent, and the conditions under which it can be expected to exert its contribution to a general campaign of control. Plans have been made for future distribution of the virus; but it is emphasized that there are many areas, such as high-value hilly country, where the rabbit is a serious pest, in which it can have little effect, and other measures of control must be pursued. Moreover, recovered animals have been found in some areas, possibly due to the appearance of virus strains of lower virulence; this opens up further questions for study, although in practice any acquired immunity, or variations in virulence, would only have temporary or local effects against the influence of fresh inoculations of the lethal strain.

Among notable instances of biological control, Australia has already provided the case of the pricklypear; it may be that this further chapter in the story of the rabbit in that continent will introduce a record of an achievement of equal or higher rank in the annals of its pastoral and agricultural development. For the moment, it is appropriate that this chapter should end by noting (*vide The Times*, October 18, 1951) that three of the scientific men who had taken leading parts in the programme, Dr. I. Clunies Ross, chairman of the Commonwealth Scientific and Industrial Research Organization, Sir Macfarlane Burnett, director of the Walter and Eliza Hall Institute, and Prof. F. J. Fenner, head of the Department of Microbiology in the Australian National University, themselves were inoculated with myxomatosis to allay doubts as to possible effects of the virus on man.

J. E. NICHOLS

RECENT RESEARCH AND ADDITIONS TO THE BRITISH FLORA

THE flora of the British Isles is probably better known than that of any other area of comparable size, and yet important discoveries can still be made. The annual exhibition meetings of the Botanical Society of the British Isles afford opportunities for bringing new plants, and the results of recent research, to the notice of botanists, and the one held in the lecture room of the British Museum (Natural History), South Kensington, on October 20 provided ample evidence that field and herbarium work in 1951 had been exceptionally productive.

The outstanding discovery of the year was that of *Diapensia lapponica* L. on a Scotch mountain, thus adding a new family—the Diapensiaceae—to the British flora. This arctic-polar species, forming dense cushion-like tufts with crowded, imbricated, cartilaginous leaves, and with peduncles some 2 cm. tall bearing solitary white flowers 1·5–2 cm. across, was discovered very locally by C. F. Tebbutt, an ornithologist, on a mountain top in Westerness. It was represented at the exhibition meeting by a fine series of photographs by J. E. Raven and by the specimen sent by the discoverer to the Royal Botanic Gardens, Kew, for identification.

Mr. Raven also exhibited photographs of *Kœnigia islandica* L., a small annual member of the Polygonaceae, with a circumboreal distribution extending as far south as the Himalayas in Central Asia. This was recently detected at Kew from specimens collected in Skye in 1934 [1] and was re-found in June this year by Miss M. McCullum Webster. Mr. Raven's photographs showed that in Skye it grows in open damp places and that it is often gregarious. His observations and pictures indicate that it extends over a much wider area than could be deduced from the notes on the labels of the Kew specimens.

Two exhibits showed species originally recorded by G. Don (1764–1814), whose "reputed discoveries" have caused so much controversy among British botanists. Of these, the most surprising was *Homogyne alpina* (L.) Cass., found by A. A. P. Slack in 1951 in "the parish of Cortachy and Clova", Angus, and shown by B. W. Ribbons. Don said it occurred in the mountains of Clova "as on a rock called Garry-barns"[2]; but hitherto no other botanist has succeeded in re-finding it. The exhibitor is anxious to obtain evidence which will help in identifying "Garrybarns". *H. alpina*, formerly known as *Tussilago alpina*, is widespread in the mountains of Europe but absent from Scandinavia. The other plant originally found by Don which was represented among the exhibits was a grass, *Roegneria doniana* (F. B. White) Melderis (*Agropyron donianum* F. B. White). Since his time this has been found at intervals in the Breadalbanes[3]; but it appears to have been seen prior to 1951 by only three living botanists, and the specimens taken by two of these remained unidentified until this summer. The species was illustrated by photographs taken by Mr. Raven in the Breadalbanes and also near Inchnadamph, where he rediscovered it after identification of an earlier unnamed specimen in E. S. Marshall's herbarium.

Among the rediscoveries, though of a different status from that of the Scotch plants just mentioned, must be classed B. W. Ribbons's exhibit of *Acanthus mollis* L. from St. Agnes, Isles of Scilly. It was recorded from here in 1851[4]; but was regarded as extinct until he re-found it recently on private ground in a place which may well have been the original station.

The exhibit provided by the Department of Botany of the British Museum (Natural History) illustrated other aspects of the present phase of rapidly increasing knowledge of our flora. It included, very appropriately, a selection of specimens from the Department's herbarium connected with papers recently published in *Watsonia*, the journal of the Botanical Society, including types of new species described therein. Among the British herbarium material displayed were: *Myriophyllum verrucosum* Lindley, *x Mentha smithiana* var. *angustifolia* R. Graham, *Epipactis pendula* C. Thomas, *Rubus watsonii* W. H. Mills, *Equisetum ramosissimum* Desf., *Epipactis cambrensis* C. Thomas, *Milium scabrum* Merlet, *Orchis cruenta* Muell., and *Scutellaria hastifolia* L. (in sequence of publication[5]). An interesting fern exhibit was *Polypodium regium* as in "Hortus cliffortianus", 1737, with specimens from Vaillant and from Clifford's herbarium, and as gathered by C. E. Salmon in Teesdale in 1892 and 1911 under the name of *Cystopteris alpina*. It does not appear to have been seen in Britain recently. Dr. A. Melderis exhibited two British grasses, *Sesleria varia* (Jacq.) Wettst. and *Phleum commutatum* Gaud., for comparison with the closely related foreign *S. cœrulea* and *P. alpinum* with which they have long been confused in Britain.

Among the exhibits by workers at the Botany School, Cambridge, were living plants of the two species of *Sesleria* mentioned above, shown by Dr. S. M. Walters. The true *S. cœrulea* (L.) Ard., which can be readily distinguished by the easily removed waxy covering to the upper leaf surface, is Scandinavian and East European; our plant, which also occurs in Iceland and Western and Central Europe, is *S. varia* (Jacq.) Wettst. The remarkable difference in the appearance of the upper leaf epidermis, including the stomata, was demonstrated with the aid of a microscope slide. Dr. Walters also exhibited live and dried material of *Alchemilla subcrenata* Buser recently discovered in Teesdale. This is a common European species for which previous records in the British literature were false identifications. A sheet of *A. obtusa* Buser was shown, collected in September 1951 from the only known British locality[6]. He also included sheets of an '*acutidens*'-type *Alchemilla* from the Ben Lawers range which seems not to be identical with any described Scandinavian, British or Alpine species.

Also from Cambridge, D. E. Allen demonstrated the four species he recognizes in the aggregate *Cardamine pratensis* in Britain. The provisional names given are: *C. dentata* Schultes ($2n = 32$), *C. fragilis* (Dégl. ex Lloyd) Bor. (chromosome number unknown), *C. pratensis* L. emend. ($2n = 56$) and *C. polemonioides* Rouy ($2n = 64$). The species are morphologically quite distinct, although the last two, at least, hybridize freely wherever they meet, and each has a different geographical range. Increase in chromosome number can be correlated with a more northerly range, a greater tolerance of acid soils, and a reduction in stature, in leaf-size (especially in the lamina of the upper leaflets) and in style-length. C. D. Pigott exhibited 'point' distribution maps of the three British species of *Thymus* based wholly on localities derived from herbarium material. It was interesting to note that further work had not greatly extended the range of the rarest species—*T. serpyllum* L. em. Mill. P. D. Sell and Dr. C. West showed specimens of eight British *Hieracia*, all local endemics, which had been recently rediscovered. In some cases, for example, that of *H. macrocarpum*, more than fifty years had elapsed since their original discovery.

Recent work at University College, Leicester, was represented by several exhibits. Prof. T. G. Tutin showed *Poa annua* and the allied *P. infirma* and *P. supina*, with an artificial hybrid between the two first-mentioned species. *P. infirma* is now known from Cornwall[7] as well as from the Channel Islands, but *P. supina* has not yet been found in Britain. Prof. Tutin also showed two subspecies of *Heracleum spondylium* from England. The English common plant is subspecies *australe* (Hartm.) Neuman, but he also found subspecies *sibiricum* (L.) A. and G. in Norfolk. They differ in flower, fruit and leaf[8]. Miss E. W. Davies had an interesting example of polyploidy in *Primula farinosa*. Swedish material examined had been found to have double the number of chromosomes of plants from Widdy Bank Fell, Durham, which differed in leaf characters. She also showed Somerset material of *Carex demissa* Hornem., *C. serotina* Mérat, and a suspected hybrid between them, and also an example of hybrid vigour in *Asplenium adiantum-nigrum*.

Blackberries have long been regarded as a puzzling critical group, and W. C. R. Watson's exhibit of *Rubus villicaulis* with a revised list of the series Subvirescentes is likely to make further changes necessary in British floras. In contrast, little work has been done on the species of *Oxalis* which occur as aliens in Britain. Dr. D. P. Young displayed herbarium material of twelve alien species in addition to the native *O. acetosella* and several varieties. Most of the names will be new to workers here. *Schœnus nigricans* is generally regarded as a plant subject to very little variation; but P. J. Newbould's dissections and diagrams show that even in this species there is much to learn. Miss J. P. Pugh showed specimens of *Dryopteris borreri* with the characters indicated and the allied species, from which it has been recently separated, for comparison. Her work has already shown that this fern occurs more widely than was suspected. P. F. Yeo showed a putative hybrid between *Polygala calcarea* and *P. vulgaris* from Somerset.

Exhibits of fresh material included twenty pots of wool aliens collected by Dr. J. G. Dony and J. E. Lousley in Bedfordshire. These were mostly of Australian origin and had been brought to Britain as seeds or fruits in wool. Some of these foreign plants are now locally common in districts where 'shoddy', in the form of waste from woollen mills, is used as a valued manure. Most of them are very sensitive to frost and unlikely to persist as weeds. P. Greenfield showed a living plant of *Cystopteris dickieana*, a fern known only from sea-caves near Aberdeen, where it may be extinct.

The organization of the work of revising the Flora of Warwickshire was demonstrated by P. S. Green. This included printed cards for recorders to use in sending in records, outline maps, circulars to contributors setting out instructions for collecting material of critical groups, and the "Flora Bulletin" for circulating information about the progress of the work. Coloured drawings of plants by Miss W. M. A. Brooke, Dr. J. T. Burgess (prepared 1879–1900), Miss H. D. Garside, Miss M. Knox, Rev. W. Keble Martin, Mrs. B. H. S. Russell and Miss P. Woodlands (from the Glasgow Natural History Society), and photographs, maps, manuscripts, books and herbarium specimens from other contributors were also displayed.

The general impression which the exhibition meeting left in my mind was that work on British field botany is progressing faster than ever before. This is no doubt primarily due to the renewed interest in taxonomy at the universities, as evidenced by the exhibits. But their research is also assisting the work of other centres of study and it is helping the amateur botanist to direct his energies to more profitable channels. As a result, field botany in Great Britain has had an exceptionally successful season.

OBITUARIES

Dr. R. G. Aitken

We have learned with much regret of the death on October 29, in his eighty-seventh year, of Dr. Robert Grant Aitken, director emeritus of the Lick Observatory, California. Born at Jackson, California, on December 31, 1864, Aitken was educated at Oakland High School and Williams College, Massachusetts. During 1891–95 he was professor of mathematics and astronomy in the College of the Pacific. In 1895 he joined the staff of the Lick Observatory, where he was to remain throughout his active career. William Joseph Hussey, professor of astronomy at Leland Stanford University, was at that time a volunteer observer at the Lick Observatory, and in 1896 he also was appointed to the staff. Aitken and Hussey almost at once embarked on a systematic survey of all stars down to magnitude 9·0 on the *B.D.* scale in the portion of the sky from the north pole to 22° south declination for the detection of double stars.

The survey was made at first with the 12-in. refractor, the great 36-in. refractor being used only to verify the duplicity of all discoveries. But soon the survey and the measures were made solely with the larger telescope. After Hussey left the Lick Observatory in 1905 to become director of the Detroit Observatory, Aitken carried on the survey alone, and eventually completed it to 18° south declination, the South African double-star observers taking over the responsibility for the remaining portion of the sky. In the course of this work, Aitken discovered 3,103 new double stars; Hussey, in his portion of the survey, had discovered 1,327. Throughout the survey an upper limit of separation of 5″ was fixed, but for more than half the new discoveries the separation was less than 1″.

Aitken did not restrict himself to discoveries of new binary systems. He re-measured each of his own stars at two subsequent epochs in order to detect orbital motion, while stars of special interest were observed more frequently. In the course of his work a large number of measures of known binaries, and particularly of those showing orbital motion, were made. He also computed a large number of orbits.

His observations were characterized by a high standard of accuracy, and the measurements of even the closest pairs were affected by only small accidental errors. Of special interest is the pair Aitken 88, which he discovered in 1901; the period of this binary system is only 12·2 years and the maximum separation 0·17″. Aitken observed it right round its orbit and computed the orbital elements, no other observations of this difficult pair being obtained by any other observer.

The homogeneous material obtained in this great survey was used by Aitken for various statistical studies. It is of interest to note that about one star in eighteen of those examined was capable of visual resolution as a binary star.

In 1932 Aitken published the "New General Catalogue of Double Stars within 120° of the North Pole". This work was planned to supplement the "General Catalogue" published by Burnham in 1900. On his retirement from the Yerkes Observatory, Burnham had turned over the material that he had collected for the revision and extension of his catalogue to Prof. Eric Doolittle, director of the Flower Observatory. After the death of Doolittle in 1920, the whole of the material was taken over by Aitken in accordance with a promise he had made to Doolittle in 1919. In this great work is given for each pair the earliest available measure and all later measures except those quoted or referred to by Burnham. The wider and fainter pairs were omitted, however, as unlikely to be physical doubles. Aitken set a limit of separation of 10″ for a pair with apparent magnitude of 9·0, with appropriate limits for brighter and fainter pairs. About thirty per cent of Burnham's pairs were thereby excluded, yet the new catalogue has 17,181 entries as compared with Burnham's 13,665.

In 1918 Aitken published "The Binary Stars", an authoritative and comprehensive survey of every aspect of double-star astronomy, which has proved invaluable both as a text-book and as a work of reference. A revised and enlarged edition was published in 1935.

The observation of double stars is of great importance for the information it provides about the masses of the stars. It remains one of the few fields of work in which observations (except for wide pairs) must be made visually. The glamour of astrophysics has unfortunately resulted in the almost complete neglect of double-star observations, at least in the northern hemisphere. Aitken was one of the great exponents of double-star astronomy in all its varied aspects; throughout his active career he pursued it with single-minded detachment, using to the full the advantages provided by the great 36-in. refractor and the excellent conditions for observation on the summit of Mount Hamilton.

Aitken was appointed associate director of the Lick Observatory in 1923 and director in 1930; he retired in 1935 with the title of director emeritus. After his retirement he continued to take a keen interest in astronomy. He was in great demand as a lecturer and was very active in the affairs of the Astronomical Society of the Pacific; at the time of his death he was chairman of its Board of Directors. He was elected an associate of the Royal Astronomical Society in 1913; he was awarded the Catherine Bruce Gold Medal of the Astronomical Society of the Pacific in 1926 and the Gold Medal of the Royal Astronomical Society in 1932. He married in 1888 Jessie, daughter of Captain W. R. Thomas, and there were three sons and a daughter of the marriage.

H. Spencer Jones

Prof. C. K. Tinkler

The death on October 25 of Prof. C. K. Tinkler, formerly professor of chemistry in King's College of Household and Social Science, University of London, will be felt as a loss in many circles, particularly in the world of women's education—a world in which he ranked as a pioneer.

Prof. Tinkler was born in 1881 and received his early education at Caterham School. It was here that he first met V. H. Mottram, who on his appointment in 1920 as professor of physiology in King's College became his colleague and close associate. Tinkler graduated from the University College of North Wales, Bangor, and afterwards went to the University of Edinburgh to work under Prof. J. J. Dobbie. In 1904 he became a lecturer in the University of Birmingham, and during the following eleven years worked intensively both in teaching and research. He published many papers on alkaloids of the berberine type and cognate compounds, made a study of fuels, and in collaboration with a fellow lecturer published a book much valued in the petroleum industry, "The Chemistry of Petroleum", by Tinkler and Challenger.

In 1915 he was appointed a reader in the University of London and head of the Chemistry Department of King's College of Household and Social Science, then the Home Science Department of King's College for Women. It was to the work and development of this College that he devoted the remaining thirty-two years of his professional career until his retirement in 1947.

To understand fully the main achievements of Prof. Tinkler's life it is necessary to look back at the history of the College with which he was so closely identified. At the time of his appointment, the College was in its infancy. Only seven years previously, in 1908, a course dealing with the scientific and social aspects of the household and institution had been run for the first time in a department of King's College for Women, a branch of King's College, Strand. In those days the idea that there could be any connexion between pure science and the mundane affairs of the kitchen and laundry was revolutionary, and still more revolutionary the idea that a liberal academic education for women could be based on subjects within their own sphere. Nevertheless, a few great men of vision, Sir John Atkins, Sir Cooper Perry, Sir Herbert Jackson and Prof. A. Smithells, were convinced of the scope and necessity for this type of education for women; they devised and initiated the course, and collected by private enterprise sufficient money to acquire a site on Campden Hill, Kensington, and to begin building a college. If any justification of their faith be required, it is to be found in the universal acceptance to-day of their ideas and in the progress and expansion that have taken place in every aspect of the field they sought to cover: for example, in the science of foods, detergents, house-heating and ventilation, and even in the study of the social and economic relationship of the home to the community and the nation.

It was by a stroke of good fortune that Prof. Tinkler became a member of the small staff in 1915, for he was imbued by the same ideas, and threw himself whole-heartedly into the task of developing the course and establishing the College and its work. His arrival took place at the opportune moment when the first instalment of the building, including the laboratories, was erected but not yet equipped. Here then was a situation calling for those qualities with which Prof. Tinkler was well endowed—organizing ability, initiative and enthusiasm born of his ever-increasing and infectious faith in the whole project.

Success came with the years: in 1920 a professorship was conferred upon him by the University of London, in 1921 the course was recognized by the University by the granting of the degree of B.Sc. (Household and Social Science), and in 1928 the College was recognized as an independent school of the University and given its present title. In the development, Prof. Tinkler was the leading spirit. His personality, combined with wisdom and knowledge, rendered him an invaluable committee member, an able representative of the College in the outside world, and the man to whom people instinctively turned for guidance in all matters, whether academic, practical, or administrative. Within his own department he applied himself from 1915 onwards to the task of devising a suitable course in chemistry to dovetail with the other subjects in the curriculum. In collaboration with Miss Helen Masters he created a course in applied chemistry unique in its scope and to the present day regarded as a model in home science departments throughout the world. The results of original work were embodied in this course from time to time. The practical work and some of the better established aspects of theory were published in two volumes: "Applied Chemistry", by Tinkler and Masters.

As a teacher, Prof. Tinkler excelled. He possessed a great store of knowledge of a wide range of practical matters and had a remarkable gift of clear exposition and a rare capacity for bridging the gap between the academic and practical aspects of his subject.

Agnes Jackman

The death is announced of Mr. J. E. Southcombe, a director of Germ Lubricants, Ltd., at the age of sixty-six. He graduated at the University of Liverpool in 1907, and after a short period of teaching in Ireland returned to Liverpool to do chemical research. He collaborated with the late Henry M. Wells in an investigation of the properties of 'fatty oils', and their use as compounding agents with mineral oils for lubrication; and afterwards specialized on 'boundary phase' lubrication problems.

NEWS and VIEWS

British Association: Officers for 1952

THE Council of the British Association announce the following appointments for 1952, which includes the annual meeting at Belfast (September 3–10): *President*, Prof. A. V. Hill; *General Treasurer*, Mr. M. G. Bennett; *General Secretaries*, Sir Richard Southwell and Dr. George Taylor; *Presidents of Sections*, *A* (Mathematics and Physics), Prof. A. M. Tyndall; *B* (Chemistry), Prof. W. Wardlaw; *C* (Geology), Dr. J. E. Richey; *D* (Zoology), Prof. A. D. Peacock; *E* (Geography), Prof. R. O. Buchanan; *F* (Economics), Prof. D. T. Jack; *G* (Engineering), Sir Ben Lockspeiser; *H* (Anthropology and Archæology), Prof. E. O. James; *I* (Physiology), Prof. R. C. Garry; *J* (Psychology), Prof. P. E. Vernon; *K* (Botany), Prof. Meirion Thomas; *L* (Education), Mr. A. L. Binns; *M* (Agriculture), Dr. N. C. Wright; *Conference of Delegates of Corresponding Societies*, Mr. J. A. S. Stendall. The Prime Minister of Northern Ireland and the Lord Mayor of Belfast will be patrons for the Belfast meeting, for which a local executive committee has been appointed under the chairmanship of the Vice-Chancellor of Queen's University, Belfast, Dr. Eric Ashby.

International Council of Scientific Unions

THE Executive Board of the International Council of Scientific Unions held its annual meeting in the rooms of the National Academy of Sciences at Washington, D.C., on October 16–17. Prof. A. von Muralt, president, was in the chair. In addition to the members of the Board, a number of American scientific men were invited to attend the meeting from the State Department, the National Academy of Sciences and various national committees, from the National Research Council and the Science Foundation. Among the items of business mention must be made of the fact that for the first time the Board allocated among the Unions the grants-in-aid for 1952 made by the United Nations Educational, Scientific and Cultural Organization. The total allowed for each category of grant was fixed by Unesco, and the internal distribution within each category by the Board. Applications for acceptance from the International Unions of Biochemistry and Scientific Psychology were deferred. A new Joint Commission on Electron Microscopy was set up, and a Committee on a Polar Year to be organized for 1957. A revised agreement with Unesco was approved. A new feature of a Board meeting was a symposium on "Development of International Co-operation in Science", at which the speakers were Prof. F. J. M. Stratton, Dr. W. A. Noyes, jun., Dr. J. N. Mukherjee, Dr. C. J. Mackenzie, Dr. Joseph B. Koepfli and Prof. A. von Muralt. Mr. William W. Rubey, chairman of the National Research Council, presided. At the close of the meeting, visits were arranged for delegates to a number of scientific institutions in Washington. Generous hospitality was offered by the National Academy of Sciences and its officers, and the Board was entertained to lunch by the Hon. James E. Webb, Under-Secretary of State.

Nature Reserve in Ross and Cromarty

THE first national nature reserve in Britain has been established by the Nature Conservancy in the County of Ross and Cromarty. A property of some 10,450 acres within the great deer forest of Kinlochewe has been purchased by private treaty and declared a nature reserve by the Conservancy. The reserve includes the woods of Coille na glas Leitre by Loch Maree (surface elevation 32 ft.) and the eastern slopes and ridges of Beinn Eighe, rising to more than 3,200 ft. The very ancient geological formations of this region are of great interest and exhibit some of their more striking features within the reserve. The mountain scenery is particularly impressive, where the white Cambrian quartzite is most prominent upon the dark torridonian sandstone. There are several small lochans and pools on the moors. The woodlands are occupied predominantly by Scots pines and birches and are of considerable scientific interest as part of a system embracing woodland and transitional moorland areas. The moorlands, which are generally very wet, reach upwards to screes and steep rocks. In the high corries and on the exposed ridges the flora is arctic–alpine in character. Among the mountain plants are: alpine bearberry, purple saxifrage, mountain azalea, alpine thrift, moss campion and the dwarf cornel. The fauna of the district includes red deer, roe deer, wild cat, pine marten, golden eagle, buzzard and ptarmigan. The reserve as a whole, with its wide range of altitudes and its various woodland, moorland and mountain top habitats, offers excellent opportunities for biological observations and research in relation to nature conservation.

M. T. Kearney Foundation of the College of Agriculture, University of California

A NEW foundation, to be known as the M. Theodore Kearney Foundation of Soil Science, has been endowed in the College of Agriculture, University of California, with the proceeds of the bequest of the late Mr. Kearney, a prominent rancher in the Fresno area in the latter part of the last century, who died in 1906, leaving his estate to the University; the endowment now amounts to 2,268,000 dollars. The Foundation will be used for the advancement of knowledge of soil science, including soil–water–plant relations, by study of the basic physics, chemistry, biology and hydrology, with particular reference to arid and semi-arid farming regions; it will also serve to strengthen the services of the University in the education and training of soil scientists and teachers of soil science and closely related subjects. Mr. Kearney's interest in soil science arose from his experience of barrenness of soils resulting from alkali accumulations following irrigation. The current programme of the College of Agriculture includes research on the physical behaviour of soils, chemical problems of alkali soils and methods of cropping on them, both in the field and the laboratory, with the view of the permanent reclamation and agricultural use of such soils. Other studies include the behaviour of important chemical ions and their uptake by plants; direct fertility studies in relation to soil types; the palatability and nutritive value to livestock of forage crops produced on soils of different fertility levels; the clay minerals of the soil and the part they play in soil chemistry and physics; and soil surveys and land classifications of the agricultural, grass and forested areas of California.

Inter-Commonwealth Postgraduate Scholarships in Science

THE Royal Society Empire Scientific Conference and the British Commonwealth Scientific Official Conference in 1946 recommended the preparation of a list of postgraduate scholarships available for scientific study within the Commonwealth. The task of compiling a list was assigned to the British Commonwealth of Nations Scientific Liaison Office in London, and it has now published the required information in a book called "The Commonwealth Post-Graduate Scholarships in Science". Since the main objective of the list is to encourage the movement of scientific workers within the Commonwealth, only those awards open to members of at least one Commonwealth country or Colony other than the awarding one have been included. The entries are set out in tabular form showing, in addition to the names of the scholarships and the agencies awarding them, details of the fields of study, where tenable, duration and value, closing dates for applications and the addresses to which these should be sent. There are more than 350 separate entries in the list: many of these cover a number of scholarships so that the total number of available awards is much greater. The list should be a valuable work of reference for students and educational authorities and is published by H.M.S.O., price 5*s*.

Costantino Gorini Foundation for Dairying, Milan

A FOUNDATION in memory of Costantino Gorini, the dairy bacteriologist, who died in September 1950 in his native city of Milan, has recently been formed, under the auspices of the Lombard Institute of Sciences and Letters of Milan, for the purpose of assisting research workers engaged in dairy science and technology, especially in the field of microbiology. Periodically, an international competition will be held and a prize awarded for results in improving the production and uses of milk and dairy products in the interest of human nutrition. Entries for the present competition, for which the prize will be 100,000 lire, must be sent in before December 31, 1952, to the Istituto Lombardo, Via Brera 28, Milan. An entry must consist of a letter of application, supporting reprints of published work and an account of the research work completed since 1949; the reprints and the letter of application may be written in Italian, French, English, Spanish or German, but the account of the work itself must be in Italian or French.

Jaina Legend in Old Gujarati

A WORK in Old Gujarati ("The Nalarayadavadanticarita (Adventures of King Nala and Davadanti)", edited and translated by Ernest Bender (*Trans. Amer. Phil. Soc.*, 40, Pt. 4, 1950) is a Jaina version of the Mahabharata story of King Nala and Queen Davadanti. Nala loses his kingdom at dicing to his younger brother and is exiled, taking the form of a hunchback at the command of his father's spirit. After adventures lasting twelve years he is reunited with Davadanti, assumes his natural form and regains his kingdom. The story is used as a discourse on the precepts of the Jaina religion, Nala's misfortunes and subsequent reinstatement being explained as the outcome of his actions in previous births. The book contains a comparison with the Mahabharata version, notes on metres and grammar, the Gujarati text in English script, and a translation, glossary and bibliography.

Isabelline Shrike on the Isle of May

IN September 1950 Miss Winifred Flower and Miss M. I. Kinnear observed on the Isle of May a shrike which did not appear to resemble any of the species described in "The Handbook of British Birds". Full details were forwarded to the late B. W. Tucker, who accepted the record as referring to the isabelline shrike (*Lanius isabellinus*). Later, Sir Norman Kinnear compared this material with specimens in the British Museum and confirmed the identification of what is a species new to the British list (*British Birds*, 44, No. 7; July 1951). The breeding-range of the species *Lanius isabellinus* extends from Transcaspia and the southern Khirgiz steppes through Turkestan and Mongolia to southern Transbaikalia and Alashan and Ordos in inner Mongolia. Various authorities are in disagreement as to the ranges of the three subspecies *L. i. isabellinus*, *L. i. phoenicuroides* and *L. i. speculigerus*, but agree that the last is found in Mongolia and Transbaikalia. On migration the isabelline shrike travels south-westward through north-western India, Persia, southern Iraq, and southern Arabia to winter in Africa from the Sudan, Abyssinia and Somaliland south to Uganda and Kenya and west to the Lake Chad region.

Acetylene Industry and Chemistry in Germany during the War

THE Department of Scientific and Industrial Research has issued a booklet entitled "The Acetylene Industry and Acetylene Chemistry in Germany during the Period 1939–1945", by Dr. R. Owens and Dr. A. W. Johnson (pp. 157; London: H.M.S.O., 1951; 3*s*. 6*d*.). This is a substantial pamphlet and gives very detailed information on all aspects of acetylene chemistry, in which important advances were made in Germany during the war period. The processes include the thermal cracking of methane and other saturated hydrocarbons, and the manipulation of acetylene under pressure. The chemical industry will undoubtedly be grateful to H.M. Stationery Office for making available (and at such a low price) a compilation of this size and content.

Proceedings of the International Conference on Low Temperature Physics

THE *Proceedings of the International Conference on Low Temperature Physics* held in Oxford during August 22–28 (see *Nature*, November 10, p. 807) are now available and are being sent out to those who ordered them at the conference. The publication consists of illustrated reports of 106 papers on 165 foolscap pages produced by the 'Rotaprint' process together with a short summary of the discussions. It is of interest to see how prompt publication of this report has been achieved. Fifty reporters, drawn from research workers in the Universities of St. Andrews, Bristol, Cambridge and Oxford and Queen Mary College, London, were used, each of whom was allotted about an hour of conference time. They were asked to write about 350–400 words, and to choose the minimum number of diagrams, for each fifteen minutes they were 'on duty', and in most cases they were confined to lectures given by people from the same laboratory as themselves. Manuscripts submitted in advance were also dealt with by the reporters on this basis. In this novel way, the organizers of the Conference were able to receive promptly short trustworthy accounts of papers presented, and also adequate reports of the actual discussions, with the result that the present useful summary has been prepared under the editorship of Dr. R. Bowers and produced within three months of the close of the Conference itself. Copies of the *Proceedings* can be obtained, price 15*s*., if orders are received by the Low Temperature Conference Secretary, Clarendon Laboratory, Oxford, before the end of the year.

Rhodes–Livingstone Museum

A SOMEWHAT unusual museum report is that of the Rhodes–Livingstone Museum in Northern Rhodesia (Pp. 44. Livingstone: Rhodes–Livingstone Museum, 1951. 2*s*.). The period covered is 1934–51, and it includes an account not only of its first home in the old Magistrate's Court in Livingstone, but also its present position in the United Services Club building, to which it moved in 1937. Finally, new buildings were completed in November 1950, mainly due to the generosity of local firms and private subscriptions. The aim in arranging the collections has been to create a friendly, pleasant atmosphere in which the visitor immediately feels at ease. Pale pastel shades predominate, and everything has been done to make a visit to the Museum a worthwhile adventure. The report also includes an excellent summary of the aims of museums in general and the policy of the Rhodes–Livingstone Museum in particular. This is a report of particular value to curators and all those who are interested in modern museum development.

University of Birmingham

DR. O. E. LOWENSTEIN, senior lecturer in zoology, University of Glasgow, has been appointed Mason professor of zoology in the University of Birmingham, in succession to Prof. P. B. Medawar. The following have been appointed lecturers in the University: Dr. H. R. Mulholland (mathematics); Dr. C. E. Harrold (botany); Dr. F. J. Wallace (mechanical engineering); and W. M. Crooks and D. C. Freshwater (chemical engineering). The following have been appointed research fellows in the University: Dr. J. M. Rushforth (mathematics); J. D. Lawson (geology); and Dr. A. R. Harding and T. Broom (metallurgy). The title of reader in thermodynamics has been conferred on Dr. F. K. Bannister, lecturer in the Department of Mechanical Engineering. Dr. R. T. W. Hall has resigned from his lectureship in chemical engineering on taking up an appointment with Esso Motor Spirit Co. at Fawley, Hants.

The Night Sky in December

FULL moon occurs on Dec. 13d. 09h. 30m., U.T., and new moon on Dec. 28d. 11h. 43m. The following conjunctions with the moon take place: Dec. 7d. 10h., Jupiter 4° S.; Dec. 22d. 23h., Saturn 6° N.; Dec. 23d. 03h., Mars 6° N.; Dec. 25d. 14h., Venus 8° N.; Dec. 27d. 06h., Mercury 8° N. In addition to these conjunctions with the moon, Mars is in conjunction with Saturn on Dec. 19d. 13h., Mars being 0·7° S. In the early part of the month Mercury sets about an hour after the sun and is in inferior conjunction with the sun on December 17, after which it becomes a morning star and at the end of the month rises nearly two hours before the sun. Venus, a morning star, rises at 3h. 20m., 3h. 55m. and 4h. 35m. on December 1, 15 and 31, respectively, stellar magnitude varying from − 3·9 to − 3·6 and the visible portion of the illuminated disk varying between 0·58 and 0·70. Mars is a morning star, rising at 1h. 40m. on December 1 and at 23h. 50m. on December 31; in the early part of the month the planet is close to η Virginis. Jupiter is visible up to about midnight, setting at 1h. 40m. and 23h. 50m. on December 1 and 31, respectively. Saturn, a morning star, rises at 2h. 25m., 1h. 40m. and 0h. 40m. at the beginning, middle and end of the month, respectively, and in the last case is a little north-west of θ Virginis. Occultations of stars brighter than magnitude 6, observations being made at Greenwich, are as follows: Dec. 3d. 18h. 26·7m., 30 Capr. (*D*); Dec. 10d. 16h. 08·5m., ε Arie. *m*. (*D*). *D* refers to disappearance. The Geminid meteors are active during the first week of December. Winter solstice occurs on Dec. 22d. 16h.

Announcements

H.R.H. THE DUKE OF EDINBURGH will open the new laboratories at Stoke-on-Trent of the British Ceramic Research Association on December 12.

PROF. ALBERT VANDEL, professor of zoology in the University of Toulouse, has been elected a *correspondant* for the Section of Anatomy and Zoology of the Paris Academy of Sciences in succession to Prof. Emile Guyénot, professor of zoology and comparative anatomy in the University of Geneva, who has been elected a non-resident member of the Academy.

THE degree of D.Sc. in the University of London has been conferred on D. R. Bates (University College), Prof. C. H. Gray (King's College Hospital Medical School) and Miss Florence N. David (University College).

THE Centre National de Coordination des Études et Recherches sur la Nutrition et l'Alimentation is arranging a symposium on meat production, to be held in Paris during December 18–20, at which scientific research workers and technologists will present papers on different aspects of the subject, both from the point of view of the producer and from that of the consumer. Further information can be obtained from the Secrétariat, Centre National de Coordination des Études et Recherches sur la Nutrition et l'Alimentation, 71 Boulevard Péreire, Paris, 17ᵉ.

THE annual exhibition of the Television Society will be held during December 28–29 at Century House, Shaftesbury Avenue, London, W.C.2. The exhibition will be open as follows: December 28, 6–9.30 p.m., members and friends; December 29, 10.30 a.m.–5.0 p.m., members. The public is admitted by invitation card. All exhibits are closely related to television engineering or production or to the production of television programmes. Tickets of admission may be obtained from Society or patron members, or from the Lecture Secretary at 10 Tantallon Road, Balham, London, S.W.12.

THE Institute of Rural Life at Home and Overseas is organizing a conference entitled "Rural Life at Home and Overseas", to be held at High Leigh, Hoddesdon, Herts, during January 1–4, 1952, under the chairmanship of the Rev. Dr. W. E. Farndale, a former president of the Methodist Conference and moderator of the Free Church Federal Council. Three lectures will be delivered: "Progress in British Agriculture", by Prof. H. G. Sanders; "A Sudan Experiment in Education", by V. L. Griffiths; and "The Church in the Village", by the Rev. A. K. Mathews. The fee for the conference (inclusive of board) is £3. Registration forms and further information can be obtained from the secretary of the Institute at 84 Eccleston Square, London, S.W.1.

ISOLATION OF NUCLEI FROM PLANT CELLS

By DR. R. BROWN

Botany Department, University of Leeds

A CHANCE observation on the effect of pectinase solutions on plant tissues has led to the development of a technique for the isolation of nuclei. This technique may have several applications, since it can be used with the root tip, which is an important experimental object, and it yields nuclei in a comparatively undamaged state.

A method that can be used with certain plant tissues has already been described by Feulgen, Behrens and Mahdihassan[1]. These workers, after grinding dry rye embryos in a specially designed mill, centrifuged the dismembered tissue in a mixture of benzene and carbon tetrachloride. During centrifugation, nuclei collected in the upper layer and other cellular components settled into the lower. With this technique after drying the nuclei, Feulgen *et al.* were able to demonstrate the presence in them of deoxyribonucleic acid. It is evident, however, that with this procedure mechanical damage is likely to be extensive, and the solvent action of the organic fluids considerable.

The technique that is being used in this laboratory has been developed primarily with onion roots. Tips about 5·0 mm. long are taken from vigorously growing roots. After excision the tips are transferred immediately to a 1·0 per cent solution (pH 6·6) of a commercial pectinase preparation, in which they are allowed to stand for three hours at 5·0° C. At the end of this period the material is transferred to a glass mortar in which it is ground lightly. The tissue breaks down rapidly, yielding a thick mush which is immediately suspended in a 1·0 per cent pectin solution. The suspension is filtered twice through a coarse sintered glass filter and finally centrifuged twice, as slowly as possible. A suspension is obtained in which the surfaces of many of the nuclei are apparently unbroken and completely free of adhering cytoplasmic fragments. The suspensions, however, are not free of cellular debris. They contain occasional fragments which limit the value of the preparations for cytochemical observations; but they are probably sufficiently clean to be used for cytological and some physiological purposes.

The pectinase treatment tends, of course, to disintegrate the wall and thus to facilitate the release of protoplast components. The separation of the nuclei from the cytoplasm is no doubt primarily simply a consequence of a loose connexion between these two components of the protoplast. At the same time, certain observations suggest that the enzyme preparation may have some effect on the cytoplasm itself. Although occasional nuclei may be obtained by grinding tissue without previous treatment, these are usually covered with a mantle of cytoplasmic threads. Further, prolonged treatment reduces markedly the yield of nuclei. It may be emphasized, however, that since the pectinase preparations used here undoubtedly contain a considerable proportion of impurities, the possibility cannot be disregarded that the apparent effect on the cytoplasm is due to substances other than the pectinase.

After grinding, the nuclei are dispersed in the fluid released from the tips. In this they remain intact for about an hour at room temperature. When they are transferred to water or to an inorganic salt solution they disintegrate immediately. Some nuclei survive for short periods in dilute solutions of citric acid. Many, however, do not, and those that do tend to have a granular abnormal appearance. It was thought in an early stage of the investigation that the possible effect of pectinase on the cytoplasm might be due to the disintegration of a polysaccharide which binds the nucleus to the cytoplasm and has a stabilizing effect on it. The effect of suspending the nuclei in a pectin solution was accordingly explored. It was found that a 1 per cent solution of a commercial pectin preparation sold for domestic jam-making preserved the nuclei for periods up to 9 hr. At the same time it was also found that a 1 per cent solution of bacteriological peptone gave the same result. Since pectin involves fewer complications than peptone, the use of a dilute solution of the former has been adopted as a standard procedure. It may be noted that the effects of pectin and peptone suggest that in the cell the stability of the interphase nucleus may be promoted by the action of certain polymers on the nuclear surface.

The filtration through sintered glass removes the bulk of the larger fragments, and the subsequent centrifugation the majority of the smaller. Slow centrifugation is important. With rapid centrifugation the nuclei tend to disintegrate into a thick, viscous mass which settles to the bottom of the tube. It has been found convenient to use a small hand-centrifuge for 6–7 minutes.

The rapid disintegration in water suggests that immediately after isolation the proteins of the nuclei are in an undenatured state. When any treatment is applied which tends to coagulate the proteins, then the nuclei remain completely stable in water. The suspensions that have so far been obtained consist almost entirely of interphase nuclei in which with normal visual light no structures other than nucleoli are discernible within them. The number of these

Isolated nuclei. × 500

varies between 1 and 4. A surface membrane cannot be identified either with the visual or the ultra-violet microscope. After isolation the nuclei behave as simple gels. They do not markedly contract or expand with changes in the osmotic pressure of the external fluid, which suggests that they do not contain a free liquid phase.

The variation within the suspension is large. The shape, optical properties and resistance to chemical treatment vary considerably. While most of the nuclei are circular in surface view, many are rod-shaped with rounded ends. Some are clear and translucent, whereas others appear to be more opaque. It appears to be the large translucent nuclei which are most unstable after isolation. Such variations are no doubt to be expected in a region such as the root tip in which the cells are in different stages of development, and in which those that are meristematic are in different phases of the division cycle.

Finally, although the technique described above has been developed with onion root tips, it has been shown that free nuclei may be obtained from root tips of other species, from mature regions of the root, and from immature leaves. From these other materials, however, suspensions relatively free from cellular components other than nuclei have not been obtained. With onion root tips the most satisfactory preparations have been obtained from young, vigorously growing roots.

The initial observation on which this work is based was made while I was a guest in the laboratory of Dr. V. M. Cutter, of the Osborn Botanical Laboratory of Yale University, and I wish to thank Dr. Cutter for his help at that time. I also have to acknowledge my indebtedness to Prof. I. Manton for considerable advice, and Mr. B. Clarke for taking the photograph which accompanies this article.

PROPERTIES AND REACTIONS OF MIXTURES OF TRIFLUOROACETIC ANHYDRIDE AND OXY-ACIDS

By Dr. E. J. BOURNE, Dr. J. E. B. RANDLES, Dr. J. C. TATLOW and Dr. J. M. TEDDER

Chemistry Department, University, Birmingham 15

FOR some time, with other colleagues, we have been studying the physical and chemical properties of mixtures of trifluoroacetic anhydride and certain oxy-acids, and our observations have now reached a stage where they may be summarized and correlated. All the data so far obtained conform with the hypothesis that, when a weak oxy-acid (HOX) and trifluoroacetic anhydride are mixed in approximately equimolecular proportions, the main product of the reaction, which is often vigorous, is the 'unsymmetric' anhydride (CF_3COOX), which exists to a small degree as the ions CF_3COO^- and X^+, as is shown in equations 1 and 2. The alternative mode of ionization into CF_3CO^+ and OX^- is improbable, because of the strong electronegative character of fluorine. We propose to present the evidence upon which this hypothesis is based.

$$\begin{array}{c}(CF_3CO)_2O + HOX \\ \updownarrow \\ CF_3COO^- + X^+ + CF_3COOH \\ \updownarrow \\ CF_3COOX + CF_3COOH\end{array}\qquad\begin{array}{r} \\ (1) \\ \\ (2) \\ \end{array}$$

If the hypothesis be true, then a mixture of an oxy-acid (HOX) and trifluoroacetic anhydride should effect substitution by the reactive electrophilic X^+ ion. For example, when HOX is a carboxylic acid (RCOOH), the mixture should furnish a source of acylium (RCO$^+$) ions, and should be a powerful acylating, rather than trifluoroacetylating, medium. In conformity with this, we have already shown experimentally that such a mixture reacts readily with hydroxy-compounds to give esters of the carboxylic acid[1,2], and with activated aromatic compounds (for example, polyalkyl benzenes, phenyl ethers, furan and thiophen) to form the corresponding ketones[3]; in neither of these two types of reaction was the formation of the trifluoroacetyl derivative observed. In an analogous fashion, mixtures of sulphonic acids and trifluoroacetic anhydride have been employed for the preparation of sulphonate esters[2] and of sulphones[3].

The introduction of basic substances has a pronounced effect on the chemical reactions of carboxylic acid – trifluoroacetic anhydride mixtures. Thus, the introduction of sodium acetate into a mixture of acetic acid and trifluoroacetic anhydride greatly reduces the acetylating power of the medium, which then forms both the acetate and trifluoroacetate esters when it is allowed to react with an alcohol[4]. Likewise, the treatment of primary amines with acetic acid and trifluoroacetic anhydride affords mixtures of the acetyl and trifluoroacetyl derivatives in which the latter frequently predominate[5]. These observed effects of bases find a logical explanation in the above theory, for the introduction of a base into the system would be expected to increase markedly the concentration of the trifluoroacetate anion, which in turn would decrease the concentration of the reactive cation (CH_3CO^+ or X^+) in favour of the molecular anhydrides [$CH_3COOCOCF_3$ and $(CF_3CO)_2O$], both of which are capable of promoting trifluoroacetylation (compare Emery and Gold[6], who studied the reactions of unsymmetric anhydrides derived from acetic acid and chloroacetic acids). The fact that sodium trifluoroacetate itself, when introduced during an esterification process involving acetic acid and trifluoroacetic anhydride, similarly increases the trifluoroacetate/acetate ratio, lends support to these arguments[4].

Evidence of the validity of our hypothesis has been obtained also by physico-chemical methods. Cryoscopic data furnished by Morgan[7] revealed that, when trifluoroacetic anhydride is dissolved in a large excess of acetic acid, each anhydride molecule gives rise to two other molecules. His results eliminated the possibility that the reaction proceeded solely according to equation 3, which requires that each trifluoroacetic anhydride molecule should afford three other molecules, but they agree with equations 1 and 2 if it be assumed that the degree of ionization of the unsymmetric anhydride is very small. We have obtained proof, by measurements of electrical conductivities, that ions are formed in mixtures of acetic acid and trifluoroacetic anhydride. The addition of acetic acid to excess trifluoroacetic anhydride, and likewise the addition of trifluoroacetic anhydride to excess acetic acid, resulted in a very marked rise in conductivity, which, although it still remained quite small, was much too large to be due to the trifluoroacetic acid formed according to equations 1 and 2, and was slightly greater than could be accounted for by the two molecules of acid formed as in equation 3.

$$(CF_3CO)_2O + 2CH_3COOH \rightleftharpoons (CH_3CO)_2O + 2CF_3COOH. \quad (3)$$

It should be noted that, for the acylation of hydroxy-compounds[6] and of anisole[7], the carboxylic acid – trifluoroacetic anhydride mixture may be replaced by one consisting of a carboxylic anhydride and trifluoroacetic acid. For use in a general method of acylation the latter mixture is less convenient, for it entails the preparation of each individual carboxylic anhydride; however, it does possess the advantage that a stoichiometric amount of trifluoroacetic acid is not required. As will be seen from equations 4 and 5, the trifluoroacetic acid which is utilized in the formation of the unsymmetric anhydride is regenerated when this anhydride reacts, for example, with an alcohol ($R'OH$). In support of the theory that the unsymmetric anhydride is an intermediate in this reaction, we have shown that aniline reacts with a mixture of acetic anhydride and trifluoroacetic acid to form both acetanilide and trifluoroacetanilide[5].

$$(RCO)_2O + CF_3COOH \rightleftharpoons RCO.O.COCF_3 + RCOOH. \quad (4)$$

$$RCO^+ + CF_3COO^- + R'OH \rightleftharpoons RCOOR' + CF_3COOH. \quad (5)$$

From the above evidence, it will be seen that there is strong factual support for our hypothesis concerning the mode of reaction between weak oxy-acids and trifluoroacetic anhydride. Since this support has been drawn from experiments in which the oxy-acid is of either the carboxylic or sulphonic type, it should not be assumed that other oxy-acids do not react in a similar fashion. Indeed, it has already been shown in these laboratories that trifluoroacetic anhydride promotes the formation of phosphate esters from phosphoric acid derivatives, of nitrate esters and nitro-compounds from nitric acid[8], and of nitrocompounds, nitroso-compounds and diazonium salts from sodium or amyl nitrites[8]. All these reactions, details of which will be published later, can be explained satisfactorily on the basis of equations 1 and 2.

We are greatly indebted to Prof. M. Stacey for his interest in this work, to Imperial Chemical Industries, Ltd. (General Chemicals Division), for part of the trifluoroacetic acid used, and to the Department of Scientific and Industrial Research for a grant towards the expenses. [June 26.

THE ELECTRICAL RESEARCH ASSOCIATION

During October 10–12 the laboratories at Perivale of the Electrical Research Association were open for general inspection by some seven hundred members of the Association and others interested in its work, this being the first time they had been on view since the official opening by the late Duke of Kent in 1935. Some of the researches of the intervening years were exhibited, though the emphasis was naturally on current work. In view of the limited size of the Laboratories themselves and of the Association's income the range of exhibits was noteworthy, and the exhibition may be expected to expedite the provision of improved facilities in the Association's accommodation at Leatherhead.

Of necessity, the presentation conformed with the organization of the Association's researches into switch and control gear, surges and transformers, insulating materials, transmission and utilization, rural electrification and wind power, space and water heating, ignition and the welding arc. In addition, the important work carried out extra-murally on magnetic materials, power plant materials, meter bearings, and electrical discharges in gases was also displayed, though necessarily in a less complete manner.

A series of introductory displays were shown which aimed at summarizing aspects of the Association's work that cut across the organizational divisions. These dealt with the important parts played by the Association in the fields of national and international co-operation, standardization, and in the study and developments of materials (including a separate exhibit on electrical discharges in gases). Other displays outlined the contributions made in education, instrumentation, earthing and the application of mathematical methods, while another indicated the valuable facilities which the library and information bureau offers to members.

Switch and Control Gear. A striking exhibit in this field was a display illustrating the genesis, development and industrial applications of two basic principles of arc extinction, namely, the axial air-blast circuit-breaker with a short, fully scoured arc-gap and the oil-filled, side-blast baffle pot, which have formed the basis of nearly all modern switchgear development in Great Britain.

Most of the present work is of a fundamental character and was well illustrated by the demonstration of the oscilloscopic, stroboscopic and spectroscopic study of low-power arcs in hydrogen, which has clarified the phenomena observed at much higher powers, and by the photographic study of arc form and movement in an axial air-blast circuit-breaker. A semi-commercial axial gas-blast breaker is being used for studying the aerodynamics of arcs in high-speed gas flow, and *Schlieren* pictures of the shock waves in cold gas flow in a nozzle were demonstrated.

Since the electrical characteristics of the circuit of which the breaker forms a part influence its operation, another display illustrated the results of a survey of the restriking voltage characteristics of British high-voltage networks.

A bridge-connected fuse of novel design giving improved performance, and a miniature electromagnetic pressure-recorder were features of the fuses laboratory. Work on contactors, air-break switchgear and flameproof electrical gear was also displayed.

Surge Phenomena. The study of surge phenomena has, as its main objective, the increased reliability of overhead transmission systems during thunderstorms. The work includes the collection of data on the occurrence of thunderstorms, the correlation of these with data on lightning faults supplied by the area electricity boards, measurement of lightning currents, the effects of lightning on insulators and substation plant, and the study of all problems associated with methods of protecting against lightning.

Demonstrations included the calibration of magnetic links (surge current indicators), the distribution of various types of surge in transformer windings, detection of transformer faults due to surges, protection of a transformer by a surge filter, and the protection of a wooden stay insulator by an air gap. Most of the recording apparatus was designed and constructed by the Association, a notable example being an automatic, three-element oscillograph for continuous recording on lines operating at voltages up to 132 kV.

Transformers. The investigation in the Association of transformer problems, other than those associated with surge phenomena, is of comparatively recent growth, but already it includes transformer noise, the experimental investigation of mechanical forces, the general study of temperature distribution, the application of the capacitor transformer to the measurement of very high transmission voltages, and various problems associated with parasitic losses. Demonstrations included investigations of mechanical forces and of temperature distribution in experimental transformers.

Transmission and Utilization. The great use made nowadays of model and analogue techniques was illustrated by a pilot network analyser suitable for steady-state and transient solutions and incorporating novel features leading to low cost and versatility, and by a model high-voltage D.C. transmission system. This has yielded important information on starting, operation and protection, which will undoubtedly facilitate progress with a pilot full-scale project, when the necessary resources are marshalled.

A diagram entitled "Control of Radio Interference" summarized the work in a field in which the Association is widely recognized as an authority, and interference measuring sets and examples of suppression components were exhibited.

The detection of incipient failure in insulation provided an interesting example of the logical development of a method of assessment of a property not itself measurable, through the following stages: study of the material for the selection of an associated measurable property, construction of precise equipment for measurement in the laboratory, and, finally, reduction to a portable and simple instrument for field use.

The sensitive recording magnetometer, now used for measuring small changes in the earth's magnetic field to permit ionospheric predictions, is a modified form of the magnetic bomb and mine locator developed during the Second World War.

Dielectric Materials. The majority of the exhibits in the section on materials illustrated various mechanisms of electrical breakdown, a subject to which the Association has made very great contributions. Ionic discharge within voids in insulation were shown by an artificial transparent cable, with a series of oscillograms, electrophotographs and photomicrographs demonstrating the behaviour of the discharges and the nature of the microscopic breakdown paths which they erode in insulation.

Electrochemical reactions due to leakage currents through materials have only recently been recognized as an important factor in breakdown. Tests were in progress on insulation 'stabilized' against such reactions by the addition of hydrogen-accepting compounds. Other electrochemical work included a study of ionic exchange reactions in paper as a means of reducing its electrical conductivity, and an investigation of reactions in electrolytic capacitors. Several compounds were exhibited, including long-chain paraffins, alcohols and ketones, which had been synthesized in the laboratory in connexion with the foregoing, or for investigations on the relation between crystal structure and dielectric behaviour.

Notable in this section was the wide range of physical methods which can be adapted to the study of electric properties. These included the development of photographic emulsions by electrolysis for detecting minute faults in insulation; the polarizing microscope applied to the study of molecular orientation in polystyrene; a vacuum torsion balance accurate to 10^{-7} gm. in 0·1 gm. for the measurement of moisture sorption; X-ray diffraction as a means of identifying compounds or for following changes in their structure; apparatus giving hydrostatic pressures up to 1,000 atmospheres for the study of structural changes; and a high-temperature furnace adapted for single-crystal growth in connexion with the study of ferro-electric compounds.

Reports and published papers indicated the major contributions to the theory of the solid state (including a new theory of superconductivity) made by leading scientific workers in this sphere under the ægis of the Electrical Research Association.

Magnetic Materials. A selection from the large number of reports available illustrated the work done on sheet steel and permanent magnet materials. Important results were obtained from the work on sheet steel at Cambridge, now concluded, and its continuance on a larger scale is being considered. On permanent magnets, X-ray studies are being made at Cambridge with the fine-beam technique on precipitation states in iron–copper–nickel alloys and alloy phase structures. At Sheffield precipitation-hardening alloys of nickel, chromium, iron, etc., and the mechanism of hysteresis are being investigated. At Nottingham the Bitter powder technique is being applied to domain structure and formation, and was demonstrated on a magnetized crystal of cobalt. Co-operative research with member organizations of the Association on the commercial production of permanent-magnet materials, including crystals, has led to the development of magnetic bodies with remarkable properties.

Power-Plant Materials. To improve generating efficiency in steam power stations, higher temperatures and pressures are being used, and the Electrical Research Association, jointly with the British Iron and Steel Research Association, supports an extensive investigation at the National Physical Laboratory on the creep and corrosion resistance of steels under these conditions. Corresponding extensions of the steam tables are naturally essential, and the Electrical Research Association, having sponsored the development of the Callendar tables from the start, has put in hand a further extension. The general nature and results of this work were illustrated by diagrams and specimens. It has been estimated that, as a result of twenty years of research and development, the increased efficiency of generation results in an annual saving of 18·5 million tons of coal.

Rural Electrification. Practical, rather than fundamental, problems are met with in the applications of electricity to agriculture, stress being placed always on the attainment of low electric loading and high load factor. The exhibits demonstrated how these essentially economic aims have been achieved in various aspects of soil- and space-heating and crop-drying by electrical methods.

Electric Power from the Wind. Photographs illustrated the type of hill usually found suitable for wind-power sites, on which studies of wind regime and wind structure have been made. The model wind-generators exhibited included one of the 100-kW. pilot plant now erected on Costa Hill, on the Orkney mainland.

Space- and Water-Heating. The work deals with the fundamental side of problems arising from the use of electricity for space- and water-heating, mainly from the domestic aspect. The major current research is an all-round study of the heat pump. One small installation using static water as a heat source is in operation at Perivale, and other work on heat sources such as the earth is in progress. A model house was on show which could be operated to show the possible saving effected during transient warming periods by the use of reflecting wall papers.

Ignition Research. Investigations on the electrical equipment of vehicles, including novel types of sparking plugs and the suppression of radio interference, constituted an important contribution to the national effort during the Second World War, and this work has continued with the support of the Ministry of Supply. A major aspect is the study of ignition by electric sparks, and this is also of considerable interest to the Safety in Mines Research Establishment of the Ministry of Fuel and Power, which maintains close liaison with the Association.

A high-speed single-transient oscillograph, giving a temporal resolution of 10^{-8} sec., has been developed by the Association for these researches and is being extensively used.

The Welding Arc. The detailed investigation of ferrous welding arcs was recently interrupted so that a study might be made of A.C. argonarc welding of non-ferrous metals. The result has been the development of a surge injector which maintains the arc with an A.C. r.m.s. voltage of less than 50, and is free from radio interference.

RHEOLOGY OF FILMS AND SURFACES

THE annual conference of the British Society of Rheology was held jointly with the local section of the Chemical Society at the Washington Singer Laboratories of the University College of the South-West of England, Exeter, during September 27–29. The conference was opened by Prof. H. T. S. Britton and by Dr. G. W. Scott Blair, president of the Society. On the afternoon of September 28 a visit was arranged to St. Mary's Abbey, Buckfast, when Brother Adam demonstrated the thixotropic breakdown and other rheological properties of honey in production processes. Papers were read by B. A. Pethica and by J. H. Schulman and M. Z. Dogan (Department of Colloid Science, Cambridge) dealing with the properties of insoluble monolayers at an air/water interface in the presence of some soluble long-chain electrolytes of strong activity. Comparison of the Langmuir isotherms for penetration of liquid-condensed chloresterol with a series of straight-chain C_{16} compounds has shown that the polar head group specificity falls off in the order:

$$SO_4^- > SO_3^- > NH_3^- > COO^+ > NMe_3^+.$$

In the case of the interaction of saponin with condensed chloresterol, where a stoichiometric complex is formed, the penetration isotherm shows a transition corresponding to the formation of a two-dimensional solid film. The areas of the saponin show a corresponding change in the transition zone.

Studies have also been made of the penetration of myristic acid by dodecylamine hydrochloride and of the properties of protein films in the presence of electrolytes in relation to the tanning industry. Prof. F. H. Garner and Dr. C. W. Nutt (Department of Chemical Engineering, Birmingham) read a paper on cybotactic phenomena at interfaces, describing experiments on the movement of droplets in viscous media. Evidence on the molecular orientation into a quasi-crystalline structure was discussed in its relation to chemical engineering phenomena, for example, mass transfer across interfaces.

E. Eisma (Netherlands) described experiments on the rheological properties of interfacial films on water. For films of high yield-stress and small viscosity the rotating disk method is suitable, while in the case of purely viscous interfaces the torsion oscillation method has an advantage.

Under the chairmanship of Prof. M. Reiner (Haifa), K. V. Shooter (Research Laboratory for the Physics and Chemistry of Surfaces, Cambridge) described the mechanism of boundary lubrication at light loads taking into account the pressure-dependence of viscosity of oil films. H. J. Bezer and Dr. R. Schnurman (Manchester Oil Refinery) discussed experiments with extreme-pressure lubricants using a four-ball apparatus of the Boerlage type. There was no evidence for a defined 'breakdown load' of a lubricant. An energy balance would appear to allow for an appreciable proportion, up to 10 per cent, of the mechanical energy to be available for the separation of electrostatic charges.

At another session, with Dr. R. N. Saal (Netherlands) in the chair, C. C. Mill (Printing and Allied Trades Research Association) spoke on the rheology of printing, mainly of letterpress and lithographic processes, the photogravure process being fundamentally different and generally simpler rheologically. There was a discussion on the significance of the phenomenon of parallel ridge formation in the ink film on rotating rollers in contact. M. R. Hopkins (British Iron and Steel Research Association) spoke on the mechanics of the coating of steel sheet with molten tin between rollers. A mathematical investigation based on arguments similar to those used in the theory of lubrication gives a relation between the coating thickness and the relevant variables for a single pair of rollers. This relation was found to be in accord with experimental results obtained with a sheet of nickel foil emerging from a bath of oil through a pair of polished stainless-steel rollers under precise conditions of test. A. de Wael and G. L. Lewis (Gestetner) read a paper on the electrical behaviour of oil-pigment dispersions. They have found that a dispersion with electrically conducting particles behaves differently according to the state of flocculation, whereas with non-conducting particles there is little difference. Conductive systems do not seem to obey Ohm's law. It is possible to correlate the electrical with the rheological behaviour. Materials exhibiting dilatancy—for example, titanium oxide in liquid paraffin—increase in conductivity during shear and rapidly decrease to a constant value on arrest of shear. In strong deflocculating media, such as carbon black in polymerized linseed oil, the dispersions with high yield values show neither conductivity nor high dielectric constant.

D. W. Jopling (Kodak, Ltd.) described apparatus with a servo-mechanism, designed to measure the rate of radial flow of a liquid between parallel surfaces, for the purpose of ascertaining the rate of swelling of colloidal films. The swelling of a film on one of the parallel surfaces alters the rate of flow between the plates, making it possible to calculate the increased thickness. E. Bielak and Dr. E. W. J. Mardles (Royal Aircraft Establishment), in a paper on the flow of liquid films over solids, reported that from experiments on the flow of drops along inclined planes and through capillaries, and on the radial spread of liquid pools over and between surfaces, anomalous flow-rates have been found. The flow behaviour over any one surface varies considerably with the chemical character of the liquid. Between surfaces, with films of thickness less than 10 μ, there is a tendency for the film to disrupt with the formation of pin holes and with a consequent onset of film plasticity and thixotropy, noted by earlier investigators with lubricants. This phenomenon appears to be significant in relation to the 'wringing' together of flats, hydraulic 'stiction' and the development of rigidity in lubricant films. E. W. J. MARDLES

MARINE BIOLOGICAL STATION ON INHACA ISLAND, MOZAMBIQUE

By MRS. OLIVE S. TATTERSALL

FOR several years certain biologists in South Africa have realized that the waters in and around Delagoa Bay are particularly favourable for work in marine biology. In spite of many difficulties, parties of students with the late Prof. C. J. van der Horst, of the University of the Witwatersrand, have paid regular visits to this area and have explored its varied collecting grounds. They found that there are particularly good centres for work along the western shores of Inhaca Island, which forms part of the eastern boundary of Delagoa Bay. There they worked under considerable difficulties, camping out on the foreshore in great heat, preyed upon by mosquitoes and working with inadequate and improvised apparatus. To-day, thanks to the generosity and sympathetic co-operation of the Government of Mozambique and to the enthusiasm of Prof. van der Horst, a remarkably fine biological station has been built on Inhaca Island.

In the early part of this year I was able to spend a few weeks working at this Station. On arrival at Lourenço Marques a small tug-boat was placed at my disposal by the Department of Maritime Services, and at 5 a.m. we left for the Island, 22 miles due east of the city. As we approached, the Island looked flat and uninteresting, and it was not until we were almost at the shore that the few native huts of the fishing village on the north-west coast of Inhaca appeared nestling at the foot of the low hills which rise close to the shore. We then turned south for about three miles when, on rounding a rocky promontory, we saw, on a flat stretch of dazzling white sand, three low white modern buildings, looking startlingly out of place in this scene which appeared never to have been touched by Western civilization.

Although there are more than four thousand Africans living on the Island, there is not a trace of any human habitation as one approaches from the sea. For the most part the western shores facing on Delagoa Bay have a short foreshore with low hills rising sharply as steep cliffs, densely covered with tropical vegetation. The site chosen for the Biological Station has a wider foreshore, and the hills behind it rise less steeply, though they are near enough to afford shelter from the east.

The Station consists of three detached buildings, connected by a paved causeway: the laboratory, with a wide shady veranda specially designed to meet the climatic conditions; the refectory, with kitchen, storehouses, dining-room and a wide veranda; and the dormitory, with comfortable cool rooms, modern sanitation, running water, shower baths and most appropriate modern furniture. The buildings are thoroughly mosquito-proofed so that one may enjoy the cool of the evenings in comfort. The whole of the cost of the buildings, water, electricity and sanitation has been borne by the Government of Mozambique, while the scientific equipment and furnishing has been provided by the University of the Witwatersrand.

Delagoa Bay is for the most part very shallow, though there are deep channels which will yield rich harvests to the dredge, and large sandbanks are exposed at low water. Here, among the weed and coral, one can find the utmost profusion of marine life—ascidians and sponges of the most wonderful colours, delicate planarians, sea anemones, nudibranchs, echinoderms and many worms and crustaceans.

The shore off the Station slowly shelves, and the sea goes out for a very great distance at low water. Then beyond the low-water level, for an equally long distance, there is water of not more than a foot in depth, so that good collecting is available at practically all stages of the tide. The littoral fauna is particularly rich, and my only regret was that I knew so little of it and that there were not enough books to enable me to identify the animals I found. It will, of course, be years before one can expect to build up an adequate library to cope with such abundance of life. In the meantime, I can imagine no finer holiday than a few weeks spent here, away from all the turmoil of the modern world, in a realm of Nature which man has not yet spoilt. Every possible facility is given by the Portuguese authorities to workers, and it is most refreshing to find such a sympathetic attitude existing in which the scientific investigator is allowed to work for the love of the work and is not hampered by the knowledge that he has to produce results at all costs. Although Inhaca may appear to be very remote, it is actually quite easy of access. The Union Castle ships call weekly at Lourenço Marques, and transport from the city to the Island is generously provided free of cost to the scientific worker by the Captain of the Port at Lourenço Marques. Fishing-boats pass daily between the Island and Lourenço Marques, and the Africans are always willing to bring goods from the mainland and to supply food cheaply.

I had no experience of dredging, for facilities for this type of collecting are not yet available; but nets are being bought, and it is hoped that before long a suitable boat will be attached to the Station to make their use possible. Judging by the shore fauna, there is no doubt that the dredge will reveal as rich a bottom fauna as any biologist could desire. The real industry of the Island is fishing, and it is an experience never to be forgotten to watch the small boats gathering at about 4 p.m. each evening off Inhaca village and transferring their day's catch to the larger boats, which will sail all through the night to deliver it in time for the early morning markets in Lourenço Marques. Many an interesting fish or other animal can be 'collected' by the biologist at these evening gatherings.

It is a brave venture to have established so fine a station in this spot, and it is to be hoped that many workers will be able to avail themselves of the unique opportunities for research which it affords.

THE BRITISH COUNCIL

REPORT FOR 1950–51

IN the annual report of the British Council for 1950–51*, which covers the year ended March 31, 1951, the general plan is that adopted for the first time in last year's report, though some of the chapter headings are different and that on the Council and the sciences disappears. A series of eleven chapters reviews in general terms the work of the Council in promoting cultural relations in four main territorial regions—Latin America, the Middle East, the Far East and the Commonwealth—then the work of the institutes, advisory visits abroad, work in the United Kingdom for the welfare of overseas students, and, finally, finance. Detail for the most part is given in a series of appendixes which occupy roughly half the report, of which those dealing with university interchange, lecturers overseas, and courses organized by the Council are of chief interest to the scientific worker.

In view of the publicity which the closing of three hostels for overseas students in Britain has received during the year, the section of the report which deals with the welfare of overseas students will be read with special interest. The scheme which the Council prepared, in consultation with the government departments concerned, for covering its wider responsibilities for the welfare of Colonial and overseas students generally for the period January 1, 1950, to March 31, 1954, was based on the view that, since it is undesirable to segregate Colonial students, hostels should not, if it could be avoided, be used by Colonial students only; and that, ideally, hostel accommodation should be regarded as a temporary necessity and that accommodation should be found for as many as possible either in permanent halls of residence, or with private families or in lodgings. Where hostel accommodation was unavoidable, it should be of a standard comparable with that of a university hall of residence.

The three hostels were closed in accordance with this policy and replaced by one residence housing 200 men, which was opened in Hans Crescent, London, in October. Planned and equipped to the standard of a modern university hall of residence, this is intended also to become a live centre for the Colonial student population of London. Those selected to spend a year there were mainly freshmen. A hostel in Edinburgh for twenty-eight men was taken over from the Colonial Office, and one for twenty-five men was re-opened in Newcastle. The small hostels in Manchester and Leeds had been established before the Council assumed its new responsibilities from the Colonial Office, and were not a part of the Colonial student welfare scheme. As a measure of economy, arrangements had to be made to close them at the end of the year; but the Leeds hostel was reprieved later through private generosity. Most Colonial students have to be accommodated in private houses, and the finding of suitable billets has not been easy. The report states that by the end of the year it was clear that additional hostel accommodation is required in London. The report stresses the value and far-reaching effects of this work; but points out that what really matters is how much the British public can be stimulated to do for such students.

Other work in the United Kingdom of particular interest to the scientific world is that of the Students Department, where the awards were re-distributed in view of the withdrawal of the Council from work in Czechoslovakia, Hungary and Bulgaria and the cessation of the flow of scholars from China. The number of scholarships for Germany and Yugoslavia was increased, and students from Burma, Indonesia and Thailand partly offset the loss of Chinese scholars. In October 1950 scholars came for the first time from India and Pakistan, the demand from India being such that for the present the field is to be restricted to candidates holding first-class honours degrees and who are to study education and public administration. In general, the proportion of applicants offering the sciences, notably medicine, economics and agriculture, is increasing. The number of bursaries, which provide opportunity for short-term intensive study in industry or the professions, was increased from 125 to 197, more than two-thirds being drawn from industry, agriculture and the social services. Five tours were organized for Greek provincial governors for the study of local government administration. New commitments in the Fellowships Section of the Visitors Department, which deals with all fellowships awarded for study in the United Kingdom by the United Nations and its Specialized Agencies, are in connexion with the International Labour Office Fellows and technical students under the Colombo Plan. Of the visitors, 258 were concerned with the social sciences, which displaced medicine (191) as the principal interest, education (147) coming third.

Departments constituting the Science Group further scientific exchanges with other countries, and as a result of last year's visit to Great Britain of the Secretary-General of the Spanish Higher Council for Scientific Research, several Spanish science students have received training in Britain and a delegation of British scientific workers attended the Higher Council's tenth annual congress at Madrid. The correction of the texts of Scandinavian scientific papers for publication in English continued on an increasing scale, and the Medical Department alone handled some sixteen hundred miscellaneous inquiries. The *British Medical Bulletin* continues to be the most successful scientific publication of the Council, and the monthly *British Medical Book List* has been launched to meet the overseas demand for a comprehensive list of this kind. In view of a comment by the Select Committee on Estimates, the size of the staff employed in the United Kingdom by the Council has been investigated by the Organization and Methods Division of the Treasury, as part of a wider inquiry into the

---

* Report on the Work of the British Council for the Year ended 31st March, 1951. Pp. v+120. (London: British Council, 1951.)

Council's organization and methods which lasted nearly two years. Only in the clerical and typing grades were any posts considered redundant by the investigators.

Besides the withdrawal from Czechoslovakia and Bulgaria, the feature of the Council's work in Europe during 1950–51 was the opening of a new branch in Düsseldorf to take over the work previously done by the cultural department of the High Commission in Germany. The European work bore a major share of the reduction made in the Council's grant-in-aid as a whole, and the European budget for 1950–51 was about £100,000 less than that for the previous year. With Latin America this budget still accounts for more than half the Council's expenditure on overseas services, though expenditure in the Middle East comes next to that in Europe in magnitude. Lack of funds compelled withdrawal from the Sudan. Outside education in its narrower sense, the report suggests that the bringing of specialists and influential visitors to Great Britain and the giving of lectures, with supporting illustrative material, on agriculture and its associated sciences are the best means of maintaining and strengthening the interest of the Middle Eastern countries in the culture and institutions of the United Kingdom. In the Far East, with the exception of China, where a marked increase in the work of the local centres at Nanking, Shanghai and Peking was noted during the year in spite of Government interference with the Council's work, the main difficulty has been lack of funds; but as regards Latin America, commenting on the value of British publications for the propagation of knowledge, the report observes that in some countries currency restrictions or complicated import requirements constitute the chief obstacle and one which the Council can do little to overcome.

The British Council is responsible for the operation of schemes for the interchange of university teachers, scholars and scientific workers under the cultural conventions into which Great Britain has entered. Thirty-nine regular interchange visits of this type are already arranged each year with Austria, Belgium, France, Italy, the Netherlands and Norway. Negotiations are proceeding with Denmark, Western Germany, Spain, Sweden and Switzerland, which would bring the total to fifty-two, while under a scheme established at the request of the Conference of the Universities of the British Commonwealth at Oxford in 1948, thirty-three university teachers from eighteen Commonwealth universities visited the United Kingdom and one scholar from Britain visited Commonwealth universities. Seventy-two scholarships were offered to British students by Austria, Belgium, Brazil, Denmark, Finland, France, Germany, Italy, the Netherlands, Norway, Persia, Portugal, Spain, Sweden and Switzerland, in return for the scholarships offered by the Council for many years to students from foreign universities. The number of advisory visits has also increased, and the report cites in illustration those to France on recent developments in stock-breeding; and visits of a team of three surgeons, led by Mr. C. Price Thomas, to Yugoslavia; of Dame Katharine Watt to India, Pakistan, Syria, Egypt, Iraq, Jordan and the Lebanon, to advise on nursing services; and of Dr. Mouat Jones to the Middle East and India, to advise on the development of technical education.

The net expenditure of the Council during 1949–50, the last year for which figures of actual expenditure are available, was £3,045,321, and the total sum available from public funds for 1950–51 was £3,233,700. There were, however, considerable changes in the distribution of expenditure, the estimates providing for major expansions in the work carried out for the Colonial Office, the Commonwealth Relations Office and Colonial Development and Welfare, and for a contraction, under instructions, of the provision for work in foreign countries of £325,000; the devaluation of sterling added a further £206,000 to this last figure. In the estimates for 1951–52, the Council has been called upon to reduce the provision for work in foreign countries by a further £364,000, although the Foreign Office is pressing for the expenditure of £49,000 on new services regarded as of the highest importance. Such reductions must entail drastic changes, and it is a matter for regret that neither in this report nor elsewhere is there any indication of a real inquiry into how far there is overlapping in the work of the British Council with that of the Central Office of Information, the Foreign Office itself, and the Overseas Service of the British Broadcasting Corporation which could be eliminated to the general advantage.

ELECTRONICS IN NUCLEAR SCIENCE AND ENGINEERING

Many visitors from overseas have been attracted to Great Britain in this Festival Year, not only to attend the Festival, but also to participate in the various supporting conferences arranged by the professional, scientific and technical institutes. The British Institution of Radio Engineers, the silver jubilee of which was to have been held last year, delayed its celebrations of this event and planned instead a Radio Convention for 1951. The Council of the Institution considered it appropriate that the Convention should aim at covering the whole field of electronics. In fact, the conference was probably the most comprehensive in its field ever to be held in Great Britain, and more than seventy papers were presented covering applications of electronics in all fields from nuclear physics to audio-frequency engineering. All the papers are being published in the *Journal* of the Institution.

The first session of the Convention was held at University College, London, during July 3 and 4 and dealt with the applications of electronics in nuclear science and engineering. The chair at these meetings was taken by Dr. Denis Taylor, of the Atomic Energy Research Establishment, Harwell, and his address, which was illustrated by lantern slides and ciné-film, was a survey of the radiation and particle detectors used in modern nucleonic instruments. The paper included a discussion of the long-term stability of the detectors used in assay and other instruments, and summarized from this point of view the relative advantages and disadvantages of Geiger–Muller counters, proportional counters and scintillation counters. In particular, the paper gave consideration to the problem of industrial instrumentation where high reliability is the first consideration. Graphs were presented showing the changes of counting efficiency of typical Geiger–Müller counters over a period of time, and it was noted that with counters filled with argon and ethyl alcohol large changes in the efficiency can occur during their working life. Some of these changes are related to photoelectric effects of the counter, variations of temperature, electrostatic effects on the window of the counter, etc.; but it was pointed out that, even when proper precautions are taken to avoid variations in the measured counting-rate due to all these effects, some fluctuations in the counting-rate outside those to be expected on statistical grounds are still obtained.

Dr. Taylor showed some typical curves for a Geiger–Müller counter and, in the cases shown, the counting-rate dropped by about 5 per cent in the first few minutes of use and then fluctuated over narrower limits during the course of the next hundred hours or more, the fluctuations being much larger than would be expected from the statistics. He pointed out that in laboratory experiments it is always possible to wait until the counter has settled down, and it is usually possible to determine the counting-rate of the unknown and a standard source and express the first result in terms of the second. This course allows all but the short-term variations to be eliminated, and very accurate measurements can then be made. However, in many instruments this second measurement with a standard leads to considerable complication and, in the case of industrial instrumentation, it is desirable to use more stable detecting elements both on the grounds of reliability and on the grounds of time-saving. Dr. Taylor showed graphs which indicate that Geiger–Müller counters using bromine as the quenching agent give an improved performance from this point of view, but that still better results can be obtained by using a counter operating in the proportional region, and he showed an apparatus of this type capable of giving a precision of measurement of ± 0·1 per cent and suitable for adaptation as an industrial instrument.

The two following papers were presented by K. Fearnside and Dr. J. E. Johnston, respectively, and dealt with various aspects of the use of radioactive tracers in industry. Mr. Fearnside reviewed the development of the beta-ray thickness gauge and described a number of preferred designs, dealing not only with the transmission gauge, but also with the back-scattering type. He gave details of the applications of these gauges in industrial work and information about their reliability and accuracy. It appears that they are already being used on a large scale, but that the obvious step of controlling the manufacturing process by a servo-mechanism operating directly from the gauge still remains to be done. The gauges in use at the present time simply measure the thickness of the manufactured material (strictly speaking, the mass per unit area, which is usually proportional to the thickness), and an attendant must make the necessary alterations to the machine if the thickness is outside the prescribed limits.

Dr. Johnston's paper covered a very wide field of applications, and the discussion which followed was equally wide. The main applications discussed were: determination of the presence of arsenic impurity in the germanium used for making crystal diodes (Dr. E. Billig, of the Laboratory of the Associated Electrical Industries, Ltd.); determination of the rate of wear of the dies used for making wire (Dr. J. W. Drinkwater, of the Thornton Research Centre); testing the uniformity of mixed cattle foods (British Oil and Cake Mills); testing the ventilation system of a factory (British Belting and Asbestos, Ltd.); and measuring the rate of wear of blast furnace linings (Mr. E. W. Voice, of the British Iron and Steel Research Association).

One of the most interesting papers presented at the conference was on the subject of the self-balancing potentiometric recorder. This instrument has proved to be one of great versatility and importance, and R. S. Medlock and W. A. Kealy in their paper gave a comprehensive review of the applications of this type of instrument in research and in industrial measurements. A large proportion of the applications discussed were those which have been developed for use in atomic energy plants—a novel example being the measurement of pile power. It is interesting to note that the self-balancing potentiometric recorder competes in many cases with the more orthodox instruments depending on the use of thermionic valve circuits, and for certain classes of problem offers a simpler and more satisfactory solution; moreover, in many cases the completed instrument is more compact.

The remaining three papers dealt more particularly with design of nucleonic instruments and were as follows: "Counting of Random Pulses," by E. H. Cooke-Yarborough; "Design of Portable Beta- and Gamma- Measuring Instruments," by E. Franklin and J. Hardwick; and "Pulse Circuits for the Millimicrosecond Range," by F. H. Wells. The paper on portable measuring instruments contained a great deal of new design data, and included details, to mention just a few of the novel ideas presented, of the use of cold-cathode valves in place of filament valves in these instruments, the replacement of the battery by a clockwork-driven electric generator, the replacement of the meter presentation system by a 'fluid light' type of indicator, and the use of infinite-life Geiger counter tubes. The majority of the instruments described were designed for use in the nuclear physics laboratory, or for field use by geologists or mining engineers, but some of the designs would be suitable for use by the civil defence authorities in the event of atomic warfare.

The paper by Mr. Wells dealt with a subject of more general interest, and gave a review of the circuit techniques used in measurements on short pulses and time intervals between pulses in the range $10^{-9} - 10^{-7}$ sec. The circuits described have been developed for use with scintillation and spark counters, and include pulse-shaping circuits, pulse generators, amplifiers, scaling circuits and oscilloscopes; and Mr. Wells gave examples of the use of these circuits for high-speed coincidence measurements, millimicrosecond time-interval measurements and fast counting. Probably the most interesting of the many circuits described is the fast coincidence circuit. This is essentially a mixer circuit, which will accept a pulse from each of two input channels and, if these pulses arrive at the same time, or within a given short time interval of each other, will give an output signal. In Mr. Wells's instrument the two input pulses are first shaped to give voltage impulses of defined duration, and these pulses are amplified so that each output pulse is of 10 V. amplitude. If, therefore, pulses from the two input channels arrive at exactly the same time, a double-amplitude pulse of 20 V. will be obtained. Hence, coincident pulses may be sorted out from non-coincident pulses by the use of a pulse-amplitude discriminator set to 15 V. following the amplifier, the output of the amplifier being the coincidence unit output-pulse. Mr. Wells gave details of a number of circuits he has built making use of this principle, and reported that the minimum coincidence resolving time readily obtainable is 10 millimicroseconds.

Protein Synthesis in Nucleated and Non-nucleated Halves of *Acetabularia mediterranea* studied with Carbon-14 Dioxide

It is generally assumed, after Caspersson[1], that the nucleus is the main centre of protein synthesis in the cell. However, this opinion is based on cytochemical and biological observations only (for example, the incapacity for sustained regeneration in many unicellular organisms), and it appeared desirable to test this assumption on biochemical grounds also.

An especially well-suited material has been found in the giant unicellular alga *Acetabularia mediterranea*, which has been extensively studied by Hämmerling[2]. The algæ were collected at the marine laboratory of Villefranche-sur-Mer, thanks to the kindness of Prof. Tregouboff, and they were grown according to Hämmerling's technique. Our biological observations concerning the extensive capacity for regeneration of nucleated fragments entirely confirm Hämmerling's; non-nucleated fragments of this alga are also able to initiate regeneration and even the formation of an umbrella. However, as Hämmerling has rightly noted, it is not easy to decide whether this corresponds to a real synthesis or to a mere elongation, due, for example, to a change in hydration.

In order to clear up this point, we carried out the following experiment: 50–100 nucleated and as many non-nucleated fragments, carefully washed and cleaned by means of a small paint-brush, were put into 12 c.c. of sterile medium (Hämmerling's) in a 50 c.c. Erlenmeyer flask; 2–4 mgm. radioactive barium carbonate (containing 1–2 μcuries of carbon-14) were placed in a small vial hanging from the stopper; radioactive carbon dioxide was liberated by adding a few drops of perchloric acid to the barium carbonate and the flask was immediately closed. The fragments thus kept in the presence of carbon-14 dioxide were exposed to the light of two 40-watt fluorescent tubes at a distance of 50 cm. After 24–38 hr., the fragments were rapidly washed free of radioactive medium, and sorted out (nucleated and non-nucleated fragments are readily distinguished, for the nucleus is located in the rhizoids of the alga).

The two groups of fragments were ground in 10 per cent trichloroacetic acid in a small homogenizer, the insoluble substances were washed once with trichloroacetic acid, and then hydrolysed for 18 hr. at 145° in 6 *N* hydrochloric acid, in sealed tubes. The amino-acids resulting from the hydrolysis of the proteins were decarboxylated with ninhydrin according to Van Slyke[3]; the carbon dioxide liberated was trapped in sodium hydroxide, then precipitated as barium carbonate, the specific radioactivity of which was determined by means of a thin-window counter.

The results of such experiments, performed with different batches of algæ that have been studied at different times after sectioning into two fragments, are given in the accompanying table.

Time since sectioning	Time of CO_2 incorporation	$\frac{\text{Specific activity of } CO_2 \text{ groups of proteins}}{\text{Specific activity of } CO_2 \text{ in the medium}} \times 100$		$\frac{\text{Specific activity of non-nucleated fragments}}{\text{Specific activity of nucleated fragments}}$
		Nucleated	Non-nucleated	
9 days	38 hr.	8·6	8·7	1·01
11 ,,	26 ,,	6·4	6·5	1·02
16 ,,	24 ,,	8·3	7·6	0·92
23 ,,	24 ,,	7·2	4·4	0·61
33 ,,	24 ,,	4·1	3·2	0·78
38 ,,	27 ,,	4·5	3·1	
		4·8	2·9	0·70

Preliminary experiments had shown that the incorporation of carbon-14 dioxide into the carboxyl groups of the amino-acids is linear for at least 48 hr.; it seems thus that we are very probably dealing with a real protein synthesis. It might be added that control experiments have conclusively shown that the whole of the carbon dioxide liberated by ninhydrin really came from protein amino-acids and that the contribution in this process of contaminating organisms is negligible.

In conclusion, it can be advanced that, contrary to the generally accepted views, but in harmony with Hämmerling's biological observations, the presence of the nucleus is not necessary for protein synthesis to continue for a considerable time. It is not until two weeks after enucleation that incorporation of carbon dioxide in the protein begins to drop; but even after more than five weeks this incorporation is very far from negligible. The fact that according to London, Shemin and Rittenberg[4] hæmin synthesis takes place in reticulocytes (that is, basophilic non-nucleated erythrocytes) and that the same is probably true for globin and other proteins (Borsook *et al.*[5]) suggests that our conclusions are probably also valid for animal cells without photosynthetic activity. Our results agree also with those of Hultin[6], Keller[7], Siekewitz and Zamecnik[8], according to which cytoplasmic microsomes rich in ribonucleic acid show the highest rate of incorporation of labelled amino-acids into proteins of all cellular fractions obtainable by differential centrifugation, including nuclei.

A Technique for taking Successive Shadowgraphs of Oat Seedlings

Owing to the great variability in growth-rate and tropic curvature of the coleoptile shown by oat (*Avena*) seedlings similarly treated, it is for many experimental purposes desirable to be able to take successive measurements of growth or curvature on the same individuals rather than on a fresh sample each time. Thus in experiments involving curvatures, in view of the difficulty in obtaining really straight seedlings to start with, doubtless partly due to nutation[1], it is most desirable to have initial records before treatment; it may also be useful to record the degree and kind of curvature at successive intervals after stimulation or application of growth substance. This is, however, unsafe, with the usual technique, in which the shadowgraphs are taken with white light, since the exposure itself induces curvature. Schneider and Went[1] therefore constructed their ingenious "photokymograph"; but this is only suitable for *decapitated* coleoptiles and for curvature but not growth measurements: it is, moreover, somewhat elaborate for routine or class use. The essence of the present technique is simply to use more-or-less panchromatic photographic paper for the successive shadowgraphs, and to make the exposures with light passed through an orange or red filter such that no phototropic or growth response can be detected even when the photographically necessary exposure is multiplied many times. These requirements have been met by the use of Kodak RP 15 "Reflex" paper and light from a tungsten filament lamp passed through a single layer of 'Chromex 2202/C10' orange cellulose acetate filter which has a cut-off at about 0·530 μ wave-length and a high transmission throughout the red. With a total intensity, at the position occupied by the seedlings, of 0·08 foot-candles, adequate shadowgraphs can be obtained with one minute's exposure. One hour's exposure of intact seedlings under these conditions has been found to cause no detectable growth response or subsequent curvature. It should therefore be safe to take a long series of successive records of the same seedlings.

With a double layer of the somewhat more red filter, 'Chromex 2436/C10', giving a cut-off at about 0·580 μ, and the somewhat higher total intensity of 0·48 foot-candles, an hour's exposure was found in one experiment to cause a slight but definite subsequent phototropic response. This indicates the importance of specifying not merely the colour but also the intensity and duration of the illumination in coleoptile experiments, a matter which is often overlooked; and it may, in fact, be doubted whether any wave-length in the visible spectrum is entirely inactive in affecting the growth and tropic curvature of the *Avena* seedling[2].

All the above results are for seedlings grown in deep red light (wave-length > 0·63 μ, total intensity about 0·17 foot-candles) and it must not be assumed that the technique developed would be safe for seedlings grown in complete darkness.

Full details of this work will be published elsewhere.

Iron/Sulphide Ratios in Corrosion by Sulphate-reducing Bacteria

THE stimulation of iron corrosion under anaerobic conditions by *Vibrio desulfuricans* is well known, and the organism has recently been shown[1] to be a facultative autotroph. Several laboratory investigations of this type of corrosion have been described[2–4]. But, to our knowledge, there has, as yet, been no published comparison of the corrosion under heterotrophic and under autotrophic conditions. We have felt that such a comparison should throw further light on the mechanism of this type of corrosion and on the explanation first proposed by von Wolzogen Kuhr[5]. This worker considered that the stimulation of corrosion was due to the utilization by the bacteria of cathodically produced hydrogen, by which the corrosion reaction would otherwise be polarized.

$$4Fe + 8H^{+} \rightarrow 4Fe^{++} + 8H \quad \text{(corrosion)}$$
$$8H + SO_4'' \rightarrow 4H_2O + S'' \quad \text{(bacteria)}$$
$$Fe^{++} + S'' \rightarrow FeS.$$

From these equations von Wolzogen Kuhr showed that, if no organic hydrogen donors were present and the hydrogen for sulphate reduction came solely from iron corrosion, then the ratio $\frac{\text{total Fe corroded}}{\text{Fe present as FeS}}$ should have a value of 4. This ratio is closely related to the ratio

$$N = \frac{\text{gm. atoms Fe corroded}}{\text{mol. } SO_4'' \text{ reduced}},$$

and this, as may be seen from the equations, should also have a value of 4, if von Wolzogen Kuhr's mechanism is correct and if no organic hydrogen donors are present. The presence of such hydrogen donors, as in heterotrophic medium, should result in additional reduction of sulphate, not accompanied by corrosion, leading to values of N lower than 4. In no case, however, should values greater than 4 occur, as this would imply more iron corrosion (and, therefore, hydrogen production) than that corresponding to the amount of sulphate reduced.

For our experiments, we used specimens of Armco ingot iron, 6·5 cm. × 1·25 cm. × 0·05 cm. These were exposed to the activity of the bacteria in test-tubes containing exactly 12 c.c. of suitable media, the test-tubes themselves being contained in closed vessels in which anaerobic conditions could be maintained. The basic medium used for experiments under autotrophic conditions was of the following composition: 1 gm. dipotassium hydrogen phosphate, 1 gm. each of ammonium and sodium sulphates, 0·1 gm. calcium chloride ($CaCl_2.6H_2O$), 2 gm. magnesium sulphate ($MgSO_4.7H_2O$) and 1 litre of water. For experiments under heterotrophic conditions, sodium lactate was added to this medium, concentrations of 2·3 gm./l. and 8·1 gm./l. being used. The *p*H of the media was about 7·1 after sterilization. The atmosphere in the anaerobic vessels consisted of nitrogen and carbon dioxide, the latter being at a partial pressure of about 0·3 atmosphere, which was maintained by a solution containing sodium carbonate, sodium bicarbonate and pyrogallol. This solution was contained in the base of the anaerobic vessels and had a *p*H of about 8·6. It also ensured oxygen-free conditions. The experiments were carried out for periods of 8–56 days. The iron specimens, after abrasion and degreasing, were weighed before the experiment and again at its conclusion, after removal of corrosion products by washing and cathodic treatment in ammonium citrate solution. Residual sulphate in the culture liquids was determined gravimetrically as barium sulphate, and the consumption of sulphate was calculated by subtraction from the original sulphate content of the medium. We were thus able to calculate values of the ratio N.

We found, under heterotrophic conditions, values of N ranging from 0·9 to 1·5. In view of the relatively large amount of easily oxidizable lactate present, this result can be regarded as in accord with expectation. In autotrophic medium, however, we obtained values from 5 to 9. By decreasing the sulphate concentration in the medium to 18 mgm./l., we were even able to obtain values of N as high as 48.

We feel that the demonstration, under autotrophic conditions and with pure cultures, of ratios greater than the theoretical limiting value predicted by von Wolzogen Kuhr's theory is of considerable interest. It indicates that, under the conditions of the experiments, only part of the hydrogen liberated in the corrosion of iron is utilized for sulphate reduction. The remainder of the hydrogen may be accounted for by: (1) evolution as hydrogen gas; (2) reduction of carbon dioxide in building up cellular material; (3) reduction of carbon dioxide to synthesize organic compounds not suitable as hydrogen donors for the bacteria. With regard to (2), the quantity of cellular material formed seemed insufficient to provide an explanation. Of the other possibilities, our present views tend to favour (1). This contention is supported by the results of mass-spectrometer analyses of samples of gas taken from the anaerobic vessels at the end of corrosion experiments. These analyses showed the presence of significant amounts of hydrogen, in the case both of autotrophic-medium and of heterotrophic-medium experiments. We have also carried out corrosion experiments in sterile autotrophic medium, under anaerobic conditions: in this case, any corrosion must necessarily be accompanied by the evolution of hydrogen. We found that the corrosion-rate in such experiments was not significantly different from that in inoculated autotrophic experiments.

It would seem, therefore, that in autotrophic medium the ratio *N* is merely a measure of the extent to which the bacteria utilize the hydrogen liberated by iron corrosion, and that no acceleration of corrosion is produced by such hydrogen utilization. Further support for this view arises from potential measurements, to be reported separately, in which we have studied the influence of inoculation with sulphate reducers on the corrosion potential taken up by an iron electrode in air-free autotrophic medium. These measurements revealed no significant cathodic depolarization. We therefore consider that the acceleration of corrosion caused by sulphate reducers in heterotrophic medium is not due to the removal of hydrogen, but to some other action of the bacteria. It seems likely that it is in virtue of their sulphide-producing action that the bacteria stimulate corrosion. This point will be dealt with further in the publication on potential measurements.

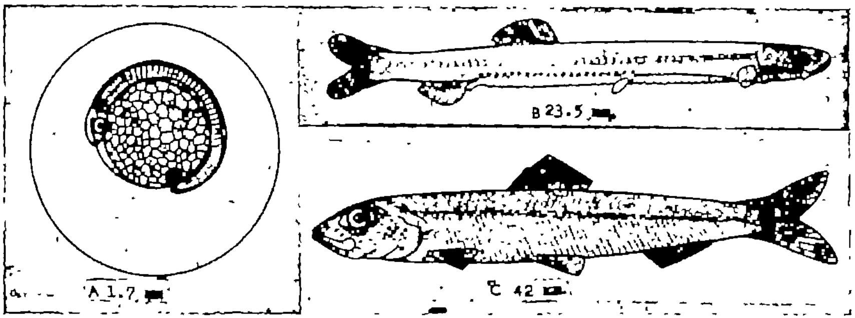
Breeding of Pilchards off the West Coast of South Africa

It was recently stated by T. J. Hart and N. B. Marshall in *Nature* of August 18 (p. 272) that the breeding ground of the pilchard, *Sardina sagax* (Jenyns), had been found off the coast of South-West Africa by the R.R.S. *William Scoresby*. Large numbers of eggs and larvæ were found in March and smaller concentrations in September of 1950.

During the course of investigations started in April 1950, and carried out by the Union of South Africa Fisheries Research Division's R.S. *Africana II*, the pilchard was found to have spawned off the west coast of South Africa over a large area. This area lies between 32° S. and 34° 25′ S., that is, between Lamberts Bay and Cape Point, a distance of approximately 140 nautical miles, and extends from 3 to 90 nautical miles from the coast in depths between 0 and 100 metres. Spawning took place over the period August 1950–February 1951.

A developmental series from the recently fertilized ovum through to the juvenile fish has been obtained. Three of these stages are shown in the accompanying illustrations.



Stages in the life-history of the pilchard (*Sardina sagax*). (*A*) Developing egg, diameter 1·7 mm.; (*B*) late post-larva, total length 23·5 mm.; (*C*) juvenile pilchard, total length 42 mm. These ova and larvæ were found under the following conditions:

	0 Metres	0–50 Metres
Temperature range	14·1–18·4° C.	11·4–18·0° C.
Salinity range	35·0–35·6‰	34·9–35·5‰
Phosphate range	0·23–0·78 P mgm.-atoms/m.³	0·30–1·45 P mgm.-atoms/m.³

Hitherto, it has been impossible to carry out artificial fertilization of the pilchard. This is due to the fact that female pilchards in a ripe and running condition have not so far been caught in South African waters. Data on counts of ova and larvæ, condition of gonads in mature fish from commercial catches and analyses of changes in condition factors show that the spawning season of the pilchard caught in South African waters is mainly in spring and summer, that is, from August to February, with greatest activity in January. It may be mentioned, however, that in no instance have large numbers of either ova or larvæ been obtained, and it is therefore thought that spawning in this area may well be incidental to the presence of great numbers of fish, and that the main focus of spawning of this species lies elsewhere. Unfortunately, no data on the South-West African pilchard are available for comparison with those of the fish caught in Union waters, and it is therefore not certain whether there are two distinct populations or a single population of varying density. The findings of the *William Scoresby* may therefore be an indication of the main spawning area of the species or another example of incidental spawning. It has shown without doubt, however, that there is a very extended area in which the pilchard may spawn.

The main planktonic organisms found in association with pilchard eggs and larvæ have been found to vary considerably. At times *Sagitta* has been the dominant organism; but eggs and larvæ have also been found in association with *Ctenophores* (*Pleurobrachia*), *Doliolum* and Copepoda. *Cladocera* have been present but only on a few occasions.

It may be mentioned that large numbers of ova, larvæ and juvenile stages of the Cape anchovy *Engraulis japonicus* (Houttyn) have been found in the St. Helena Bay area 1–100 nautical miles offshore. This may prove to be the main spawning ground of this species.

Antennæ and Mating Behaviour in *Drosophila melanogaster*

THE gene 'antennaless' of *Drosophila melanogaster* does not necessarily express itself fully in individuals homozygous for it[1]. In the course of a programme of work designed to isolate, by means of inbreeding and/or selection, a series of families all homozygous for this gene, but differing in degree of exhibition by reason of the various gene milieux present in the various families, it was noticed that high exhibition lines were conspicuously difficult to maintain. In view of the known chemoreceptive function of the antennæ in insects in general[2] and in *Drosophila* in particular[3], and the importance of the antennæ in the mating behaviour patterns of various species, experiments were started to see whether the poor results obtained with high exhibition lines could be ascribed to failure of adequate mating responses consequent upon absence of stimuli normally reaching the animal *via* these organs. Evidence that males were attracted to females by olfactory stimuli had not been obtained in previous experiments[3].

Three main types of individuals occur in cultures of antennaless stock: those with two antennæ (A_2), one antenna (A_1) and no antennæ (A_0). It is thus possible to set up nine different sorts of mating with respect to two parents. One hundred such 1 × 1 matings were tried for each mating type, and the percentage of successful (that is, fertile) matings was recorded. Results are shown in Table 1.

Table 1

Mating	Total crosses	Successful matings (per cent)
A_0 ♂ × A_0 ♀	100	6
A_1 ♂ × A_0 ♀	100	31
A_2 ♂ × A_0 ♀	100	46
A_0 ♂ × A_1 ♀	100	44
A_1 ♂ × A_1 ♀	100	63
A_2 ♂ × A_1 ♀	100	69
A_0 ♂ × A_2 ♀	100	32
A_1 ♂ × A_2 ♀	100	72
A_2 ♂ × A_2 ♀	100	75

Statistical analysis indicates that it matters little whether an animal has one or two antennæ. What is important is that it should possess at least one antenna. This point is perhaps best made by arranging the crosses in terms of whether neither, one or both parents are antennaless. Such an arrangement is shown in Table 2, where A^- represents a male or female without antennæ, A^+ a male or female with one or two antennæ.

Table 2

Mating	Successful matings (per cent)
$A^- \times A^-$	6
$A^- \times A^+$	31–46
$A^+ \times A^+$	63–75

If we leave aside at present the rather unlikely possibility that the suppression of antennæ in an individual fly is always associated with a corresponding structural or physiological abnormality of the sexual apparatus, we must conclude that the antennæ in *Drosophila* play an important, but as yet undetermined, part in mating behaviour. Their precise function is being investigated at present, and results will be fully published elsewhere.

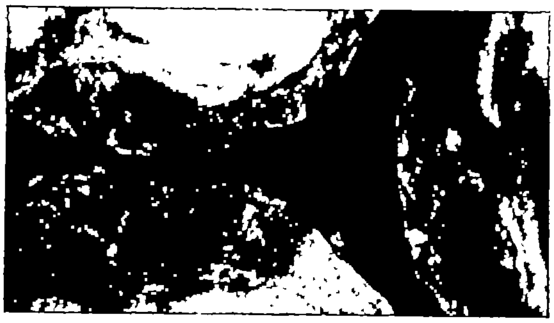
An *Odostomia* attacking Oysters

A DETAILED account has recently been given[1] of the structure and mode of life of several members of the Pyramidellidæ. It has been shown that they are parasitic and feed by sucking the juices of lamellibranchs and tube worms. The normal hosts are known for only a small number of species, principally of the genus *Odostomia*.

The first species recognized as a parasite was *Odostomia eulimoides*, stated by Jeffreys[2] to occur "chiefly (if not only) on the ears of *Pecten opercularis* and *P. maximus*, in the coralline zone; it is widely distributed and rather common". This description of its mode of life was repeated by Fretter and Graham in their review of the family. It was of interest, therefore, to find the same species attacking oysters in the River Roach, Essex. A sample of a hundred two-year-old native brood oysters dredged from near Paglesham in early June 1951 contained no less than 46 which showed evidence of attack, and many of them actually contained living *Odostomia* when opened at Conway.

The parasites were lodged in small pockets just inside the ventral margin of the shell (see photograph). These pockets result from the withdrawal of the mantle in response to the irritation caused by the proboscis of the parasite during feeding. Apparently the parasites are sedentary, and as a result of continual attack at one point both the right and left mantles are more or less permanently withdrawn for a short distance from the free edge of the shell. In consequence, new shell is laid down in an arc some distance inside the ventral margin and a permanent pocket develops. The parasites occurred mainly in pairs; but in one pocket three were found. Several pockets contained no parasites; but as the oysters had been dredged in Essex, washed, packed and dispatched by post to Conway, some loss during these processes must be expected.

Normally, only one pair of parasites occurred in a single oyster, but one was found with two pockets



Ventral margins of three shells of *Ostrea edulis* attacked by *Odostomia eulimoides*. The parasites are shown *in situ* with hatching spawn alongside. × 2

each containing a pair of *Odostomia*. In many pockets spawn had been deposited and was about to hatch; it appears as a fine granular deposit alongside the parasites.

Although *Odostomia* cannot be regarded as a major parasite of oysters, its attack on the scale recorded must result in considerable irritation, some loss of condition and possibly small permanent malformations. That the irritation is intense is shown by the deposit of patches of conchiolin at the points of attack; such deposits are also laid down in oysters heavily attacked by *Polydora*[3].

It is interesting to note that, in the River Roach, species of *Pecten* or *Chlamys*, the usual hosts of *Odostomia eulimoides*, are absent; apparently it can attack a wide range of lamellibranch molluscs.

I am indebted to Dr. Vera Fretter for the determination of the species of the parasite and to Mr. H. P. Sherwood for the photograph.

Colour Vision of an Albino

According to Gates[1] the frequency of pure albinos is about 1 in 15–25,000 of the population in Scotland. Owing to the kindness of Miss E. C. MacQuade, an albino woman aged about 45–50 years was brought for colour vision tests. She was a pure albino, according to Gates's classification, having cream-white hair, eyebrows and eyelashes, and only a very slight trace of pigment in the iris. She had a continuous nystagmus owing to photophobia, and a divergent squint, for the same reason, using mainly the left eye while the unused eye wandered. She was very short-sighted. Her mother had fifteen children, seven boys and eight girls. She and a younger sister, now deceased, were the only albinos known among all her relations.

Her colour vision was tested with Pickford's four-colour test[2] and the Ishihara test. She was almost red anomalous, without darkening of the red, since the Rayleigh equation for her fell between those of the normal and of the red anomalous shown by Pickford in his Diagram 32 [2]. Her red–green matching range was normal, but she was on the first occasion of testing a yellow deviant. On the second occasion, about three weeks later, her red–green vision was the same, but she was now very blue–yellow weak, with three times the blue–yellow modal matching range. She failed on the Ishihara test, with 15 errors on 24 plates.

Her son and one sister were also tested, and their colour vision was quite normal. Owing to death, age, infirmity or difficulties due to residence and occupation, it was not possible to test any more of her relatives at the time, though further efforts will be made. It is impossible to say definitely whether the red anomaly and the blue–yellow weakness were due to the effects of the albinism or separately inherited.

The *Rh* Chromosome C^wdE (R_y^w) occurring in Three Generations

Fisher and Race[1] postulated the existence of the gene combination CdE, and to date four examples have been found (van der Bosch[2], Wiener[3] and Johnson[4]).

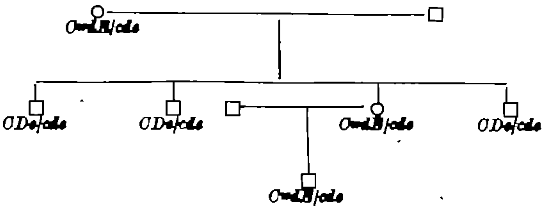
Race *et al.*[5], after reporting the discovery of the Willis antigen, further postulated the existence of the combination C^wdE, but until now this exceedingly rare blood group has not been found. This communication reports the finding of the genotype C^wdE in three generations.

The blood of the propositus—Mrs. "O", an antenatal case—gave no reaction with anti-D sera but was agglutinated with anti-C, anti-E and anti-c. Therefore, her genotype was either Cde/cdE or CdE/cde, which are serologically indistinguishable. Samples of blood from her relatives were investigated with all available sera, including anti-C^w, and a study of the results showed her to be of the genotype C^wdE/cde.

The possibility of the propositus or her relatives having a D^u antigen (Stratton[6]) was excluded by testing their cells with a series of twenty incomplete anti-D's followed by anti-human globulin serum to detect sensitization.

In forecasting the genotype CdE/cde, Fisher[1] estimated its frequency should be about 37 in a million, or that one in eight of bloods behaving as Cde/cdE would, in fact, be CdE/cde. It is interesting to note that we have examined bloods from the families of seven persons behaving as Cde/cdE or CdE/cde, and Mrs. "O" is the first of the type CdE/cde to be found among them.

The frequency of Mrs. "O's" Rhesus genotype can only be estimated approximately. In its commoner combinations, the C^w allelomorph is about fifty times less frequent than C, so on this basis the chromosome C^wdE should occur about twice in a million. There



are, however, no strong grounds for expecting the same proportion in the rarer groups; and until we know more, perhaps as many as one in five of the rare chromosomes *CdE* should be regarded as C^wdE.

Mrs. "O'g" blood groups are: O, H+ve, C^wdE/cde, $MsNS$, P, $Le(a-b+)$, $Lu(a-)$, kk, $Jk(a+)$.

We should like to express our thanks to Lieut.-Col. R. H. Malone, director of these laboratories, for permission to publish this communication, to Dr. R. R. Race for his criticism, to Prof. R. A. Fisher for his advice on frequencies, and to Miss E. W. Ikin, Blood Group Reference Laboratory, Lister Institute, London, for confirmation of our findings.

Note added in proof. Since submitting this communication for publication, the *Rh* chromosome *CdE* (R_y) has been proved to exist in two other families; see Grove-Rasmussen, M., *et al.*, *Ann. Eug.*, 16, Pt. 2, 131 (1951); and Sussman, L. N., and Wald, N., *Amer. J. Hum. Genet.*, 2, 85 (1950).

Relative Importance of Free α- and ε-Amino Groups for the Biological Activity of the Growth Hormone

THE biological activity of growth hormone[1] is found to be greatly reduced following treatment with acetic anhydride, which is known to acetylate protein amino groups specifically[2]. The relative importance of free α- and ε-amino groups has not hitherto been investigated. Purified growth hormone has now been acetylated according to the conditions of Li and Evans[1], but with smaller amounts of acetic anhydride so as to avoid complete inactivation.

The fluorodinitrobenzene technique of Sanger[3] was applied to untreated growth hormone in the first instance. The α-dinitrophenyl amino-acids liberated by acid hydrolysis were extracted with ether, and, after passage through a silica gel column, were identified by paper chromatography as dinitrophenylalanine and phenylalanine, in accordance with the results obtained by Li and Porter[4] in a preliminary study of the terminal amino groups of growth hormone. Spectrophotometric determination of the α-dinitrophenyl amino-acids was carried out on the eluate from the column. The ε-dinitrophenyl lysine hydrochloride remaining in the ether-extracted hydrolysate was estimated spectrophotometrically after passage through an acidic silica gel column.

DATA FOR ACETYLATED GROWTH-HORMONE PREPARATIONS

Acetic anhydride moles per mole of growth hormone	Residual free amino groups per mole of growth hormone*		Growth-promoting potency, % of original potency
	Alanine + phenylalanine	Lysine (ε)	
—	1·4	19	(100)
120	<0·1	15·5	53
800	<0·1	13·5	20
2,700	<0 1	9·5	11

* Not corrected for losses in hydrolysis, etc.

When acetylation was performed with a relatively small amount of acetic anhydride, no α-dinitrophenyl amino-acids could be detected following fluorodinitrobenzene treatment of the acetylated product (see table). There was, however, only a partial reduction in the ε-dinitrophenyl lysine content of the hydrolysate and only partial loss of growth-promoting activity (assayed in intact female rats[5]). With larger quantities of acetic anhydride, there was a marked lowering of growth-promoting activity concomitant with increased acetylation of ε-amino groups, as shown by the ε-dinitrophenyl lysine determinations (see table). It thus appears that the growth-promoting activity of the growth hormone depends on the integrity of the ε-amino groups, but not on that of the terminal α-amino groups. The acetylated products were assayed for diabetogenic activity in the intact cat, as will be reported elsewhere. The results indicated that the diabetogenic activity of growth hormone also depends on the presence of ε-amino groups, but not on that of the α-amino groups.

The finding that acetic anhydride can be employed to acetylate selectively the free α-amino groups of growth hormone may be applicable to other proteins possessing both free α-amino groups and free ε-amino groups.

I am indebted to the Beit Memorial Trust for the award of a fellowship, to Dr. F. Sanger for advice on the use of his technique, and to Prof. F. G. Young for helpful advice and criticism.

Bacterial Enzyme Preparations oxidizing Inositol and their Inhibition by Colchicine

PREVIOUS studies in this laboratory have brought to light a number of regularities governing the oxidation of isomers of the inositol group by resting *Acetobacter suboxydans*[1,2]. If the hexahydroxy *cyclo*hexanes are formulated as existing in the chair configuration, the minimum steric requirements for the oxidation of the various isomers by the resting cells are described in the statement that only those hydroxyl groups are oxidized that are situated in a polar plane.

The study of many aspects of these oxidative reactions required enzyme preparations in the cell-free state[3]. A thick suspension in 1/15 *M* phosphate buffer (*p*H 6·4) of the organisms, grown and harvested as described previously[1], was passed through a bacterial mill (Unicam, Cambridge). About one-half of the cells was broken. After centrifugation of the mixture (30 min., 2,000 *g*) and re-extraction of the sediment with buffer on a vibrator (60 vibrations per sec.) for 12 hr., followed by an intermediate centrifugation cycle at 11,000 *g* (1 hr.), the combined supernatants were finally centrifuged at 20,000 *g* for 2 hr. The reddish-brown pellet was suspended in phosphate buffer of *p*H 6·4. All operations were carried out in the cold.

The oxidation of glucose to gluconic acid and of sorbitol to sorbose are among the well-known activities of resting *Acetobacter suboxydans*. The first function was retained in the cell-free enzyme preparations. Glucose was attacked with the consumption of 1 gm.-atom of oxygen per mole of substrate. During the oxidation the *p*H changed from 6·4 to 5·8; neither carbon dioxide nor lactic acid was formed. Sorbitol, however, was not oxidized.

The abilities of the organisms to oxidize *meso*-, *d*- and *epi*-inositol, *d*-quercitol and *dl*-*epi*-inosose all were preserved in the cell-free enzyme preparation, but not without the presence of an additional factor, which was, however, not required for the oxidation of glucose. Suspensions of the pellet alone oxidized *meso*-inositol only very slowly. The addition of washed, heat-inactivated *Acetobacter* cells accelerated the reaction very markedly. 1 gm.-atom of oxygen was consumed by 1 mole of *meso*-inositol. Although the monocarbonyl or dicarbonyl derivatives, previously shown to be formed from the various stereoisomers by the resting organisms[3,4,5], were not isolated, the manometric experiments left little doubt that the same reaction products were formed by the isolated enzyme system. The latter, as was previously also found with resting cells[6], failed to attack pinitol, a methyl ether of *d*-inositol.

The enzyme preparations were completely inactivated by heating (20 min., 80°). The *p*H optimum at 36° (in phosphate or veronal buffer) was at 6·4. The Michaelis constant was 0·0036 *M* (compare curve *A* in Fig. 1). Saturation of the enzyme system was achieved when 3–4 mgm. (dry weight) of the enzyme preparation and 20–30 mgm. of heat-inactivated cells were contained in 3 c.c. of a 0·0365 *M* solution of *meso*-inositol in buffer. Potassium cyanide, in a 0·001 *M* concentration, totally inhibited the enzyme system.

What appears to be a more specific inhibition was discovered when it was found that colchicine and some related compounds containing a seven-membered ring prevented the oxidation of the inositols, but not of glucose, by the isolated enzyme preparations. (No effect on intact resting organisms was observed, owing, probably, to the slowness of permeation.) Several representative experiments are assembled in Figs. 1 and 2. This inhibition seems to be non-competitive. Both the slopes and the intercepts increased with increasing concentrations of colchicine, when the reciprocals of the velocity constants were plotted against the reciprocals of substrate concentration (Fig. 1). Experiments with varying concentrations of the components of the complete enzyme system showed that the effect of colchicine was exerted on the cell-free enzyme itself and not on the additional heat-stable factor. A fivefold increase in the concentration of the latter doubled the rate of oxygen uptake, but scarcely changed the extent of inhibition.

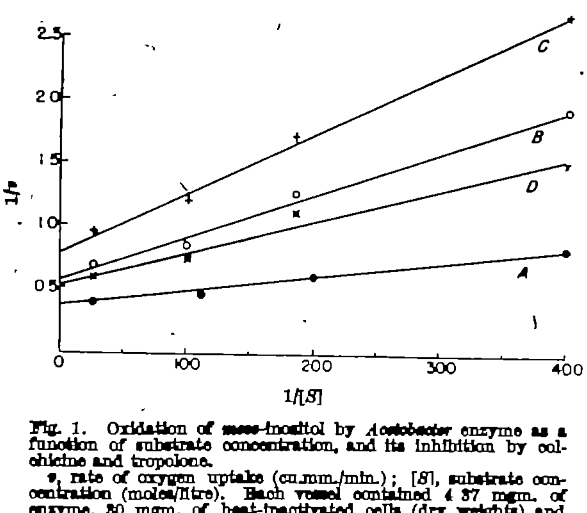

Fig. 1. Oxidation of *meso*-inositol by *Acetobacter* enzyme as a function of substrate concentration, and its inhibition by colchicine and tropolone.

v, rate of oxygen uptake (cu.mm./min.); [*S*], substrate concentration (moles/litre). Each vessel contained 4·37 mgm. of enzyme, 30 mgm. of heat-inactivated cells (dry weights) and varying amounts of substrate in a total volume of 3 c.c. of 1/15 *M* phosphate buffer (*p*H 6·4, 36°). Curve *A*, no inhibitor; curve *B*, 0·0033 *M* colchicine; curve *C*, 0·0066 *M* colchicine; curve *D*, 0·0056 *M* tropolone. In the inhibition experiments, the enzyme was left in contact with the inhibitor for 20 min. at 36°, before the substrate was added

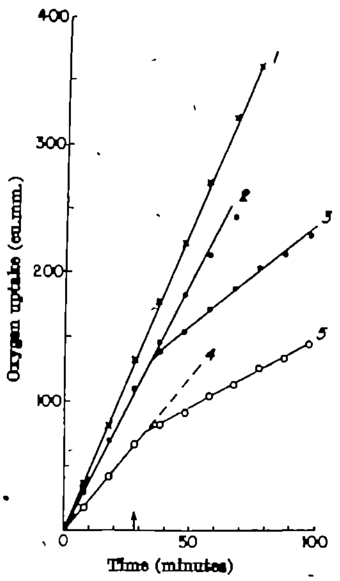

Fig. 2. Effect of colchicine on the oxidation of glucose (curve 1), *meso*-inositol (curves 2 and 3), and *d*-inositol (curves 4 and 5) by *Acetobacter* enzyme.

Each vessel contained 3·8 mgm. of enzyme and 25 mgm. of heat-inactivated cells (dry weights) in 3 c.c. of buffer. The concentration of colchicine, added 28 min. after the beginning of the experiments (indicated by arrow), was 0·0067 *M*. Substrate concentrations: glucose, 0·019 *M* (curve 1, with and without inhibitor); *meso*-inositol, 0·0089 *M* (curve 2 without, curve 3 with inhibitor); *d*-inositol, 0·0081 *M* (curve 4 without, curve 5 with inhibitor)

Preliminary results indicate that simpler *cyclo*heptane derivatives[6], namely, tropolone[7–9] and 4,5-tetramethylene tropolone, have a similar inhibiting effect on the oxidation of inositols (compare curve *D* in Fig. 1). At the level of enzyme-saturation, tropolone inhibited the system almost completely at a 0·011 *M* concentration and to the extent of 60 per cent at a 0·0056 *M* concentration; 0·0067 *M* colchicine showed a 70 per cent inhibition. The oxidation of smaller quantities of substrate (0·018 *M* *meso*-inositol solution) was completely blocked by 0·006 *M* colchicine.

It would be premature to construct analogies between the effects described here and the well-known action of colchicine as a mitotic poison. It may, however, not be entirely irrelevant that recent work in this laboratory has shown *meso*-inositol to have a specific effect in preventing colchicine from producing metaphase arrest[10,11].

We are greatly indebted to Drs. Doering and Knox for supplying the tropolone specimens and to Hoffmann–LaRoche, Basle and Nutley, for a supply of colchicine. This work, which will be presented in detail at a later date, has been supported by grants from the American Cancer Society, on the recommendation of the National Research Council Committee on Growth, and from the Nutrition Foundation.

Dephosphorylation of Adenosine Triphosphate in Muscular Contraction

CONTEMPORARY views on the role of adenosine triphosphate in contractile activity include the assumption that the breakdown of this substance is the immediate chemical source for mechanical energy[1,2]. However, as has recently been emphasized by A. V. Hill[3], there is no proof that such a dephosphorylation occurs as an early event in contraction. Furthermore, it has been shown[4] that the effects of adenosine triphosphate upon certain physical properties of actomyosin do not primarily involve splitting of the nucleotide. The experiments reported here were undertaken in order to decide whether, indeed, any dephosphorylation of adenosine triphosphate occurs during the contractile phase of a twitch.

It appears unfavourable to attempt the detection of a diminution of adenosine triphosphate by analysis of the hydrolysable phosphate (compare Lundsgaard[5]), since one would have to evaluate small differences between large numbers, which might furthermore be distorted by the formation of other labile phosphate compounds. Instead, we have employed a chromatographic assay method, closely resembling that of Cohn[6], to determine adenosine mono-, di- and triphosphate separately by their ultra-violet absorption.

The experiments were carried out with the combined leg muscles of frogs. Muscles from the two legs were isolated, care being taken to subject the two sets to the same manipulations. Starting at a temperature of about 20° C., one set was immediately extracted with ice-cold 1 *N* perchloric acid, whereas the other set was fixed at the height of contraction by sudden submersion into liquid air (compare Lundsgaard[5]). The results are shown in the accompanying table.

It is seen that in contraction there is a pronounced decrease of adenosine triphosphate, and that its breakdown goes in part beyond the stage of the diphosphate, probably by the myokinase mechanism. The decrease of adenosine triphosphate averages about one-fifth of the total nucleotide, which is about twice the expected amount[7]. If confirmed, this would indicate that precipitous cooling mobilizes the contractile apparatus to a somewhat greater extent than occurs physiologically in a single twitch, or else that in this mode of stimulation part of the muscle twitches more than once. We intend to study various other ways of eliciting contraction in different types of muscles.

DISTRIBUTION OF ADENINE NUCLEOTIDES AS A PERCENTAGE OF THE TOTAL NUCLEOTIDE FRACTION, FOR FROG MUSCLE AND (LAST LINE) FOR RABBIT PSOAS MUSCLE

Control			Contracted			Difference

In sustained muscular activity, and possibly also in a completely reversed twitch, a breakdown of phosphocreatine rather than of adenosine triphosphate is generally detected (see ref. 2). Our present results suggest, however, that it is primarily adenosine triphosphate which is dephosphorylated in the contractile phase. Apparently, a transfer of phosphate from phosphocreatine to adenosine di- and monophosphate by the Lohmann reaction[8] occurs only in later phases of the contractile cycle. We suggest that actually the Lohmann reaction is specifically connected with relaxation.

This investigation was supported by a research grant, No. H-229, from the National Heart Institute of the National Institutes of Health, U.S. Public Health Service, and was done during the tenure of an Established Investigatorship of the American Heart Association.

Transaminases in *Neurospora crassa*

THE presence of a wide range of transaminases in both animal tissues[1] and bacteria[2] has recently been reported. A rather similar array of enzymes appears to be present in the mould *Neurospora crassa*.

Mycelium of the wild-type strain *E5297a* was grown for three days at 25° in 'minimal' Fries No. 3 medium, and cell-free extracts were obtained by grinding with phosphate buffer and powdered glass followed by centrifugation as described in detail elsewhere[3]. The extracts, which were free of large particles but turbid owing to the presence of small particles just visible under the high power of the microscope, were dialysed against cold $M/15$ phosphate at *p*H 7·4. Dialysed extracts contained about 1 mgm. of nitrogen per ml.

The formation of glutamate following the incubation of extracts with α-ketoglutarate and different amino-acids was shown by paper chromatography of the deproteinized digests[4], phenol saturated with water being used as the running solvent. It was possible to obtain a roughly quantitative estimate of the glutamate formed by visual comparison of the experimental glutamate spots with a graded series of glutamate standards chromatographed under identical conditions. Glutamate concentrations were recorded as either intermediate between two standards or as approximately equal to one of the standards when they could not be seen to differ from it in intensity.

Table 1. Test-tubes each containing: 0·45 ml. $M/15$ L-Amino-acid; 0·15 ml. $M/5$ Sodium α-Ketoglutarate at *p*H 7; 0·40 ml. Mycelial Extract Dialysed against $M/15$ Phosphate at *p*H 7·4. Incubation at 34° for 3 hr.

Amino-acid	Conc. of glutamate (millimoles/l.)	Amino-acid	Conc. of glutamate
Water control		L-Tryptophan	2–3
(a) Zero time	0	DL-Methionine	3
(b) Incubated	1–2	DL-α-Aminobutyric acid	4–6
Glycine	2	DL-*nor*Valine	6
L-Lysine	1–2	DL-Valine	10
L-Serine	1–2	DL-*nor*Leucine	10
DL-Threonine	1–2	L-*iso*Leucine	10–13
L-Proline	1–2	L-Leucine	10–13
L-Cysteine	1–2	L-Aspartate	13*
L-Histidine	2	L-Alanine	16†

* Some alanine also formed. † Approximating to 50 per cent transamination.

All amino-acids tested showed some degree of transamination except glycine, serine, threonine, lysine, histidine and cysteine, which, if they reacted at all, gave less than 3 per cent transamination during three hours. The apparent small formation of glutamate in the cases of methionine and tryptophan was confirmed in repeated experiments. It has been found repeatedly that incubation of *Neurospora* extracts with α-ketoglutarate and ammonium chloride yields no glutamate under the conditions of these experiments.

To determine whether the transaminases were attached to particles (as found by Hird and Rowsell) or present in solution, a turbid extract obtained by the usual procedure was filtered by suction through a 4-mm. pad of kieselguhr to give an opalescent solution free of particles. As shown in Table 2, the greater part of all the transaminases tested were found to be present in the filtrate; part, at least, of the loss of activity on filtration can be attributed to dilution by moisture present in the filter pad. This experiment, and many others involving relatively short incubation times, shows that transamination at *p*H 7·4 is most rapid with alanine as the amino donor.

In addition to the amino-acids listed in the tables, ornithine has been shown to be acted upon by a *Neurospora* transaminase, its effectiveness as an amino donor being about equal to that of *nor*valine in the type of experiment outlined above.

It was found that amino-group transfer to α-ketoglutarate from *iso*leucine, ornithine or phenylalanine was more rapid at *p*H 8 than at either *p*H 7 or *p*H 9, while in the case of aspartate the reaction was rather more rapid at *p*H 9 than at *p*H 8. At *p*H 9 aspartate reacted faster than alanine. The behaviour of alanine was strikingly different, the apparent optimum *p*H in this case being in the region of 5·5–6·0. The formation of glutamate from alanine and α-ketoglutarate was, at initial *p*H 5·5–6·0, accompanied by a rise in *p*H of about one unit, and it seems likely that the rate of decarboxylation of pyruvate was a factor contributing to the rate of transamination.

Table 2. Test-tubes each containing 0·3 ml. $M/15$ L-Amino-acid, 0·1 ml. $M/5$ Sodium α-Ketoglutarate, and 0·2 ml. Extract buffered as in Table 1. Incubation at 34° for 1 hr.

Amino-acid	Conc. of glutamate formed (millimoles/l.)	
	Extract filtered	Extract unfiltered
Water control	1	1–2
L-Alanine	12	15
DL-α-Aminobutyric acid	3–4	4
DL-*nor*Valine	4	6
DL-Valine	8–10	10
DL-*nor*Leucine	5–6	6
L-Leucine	6	8–10
L-*iso*Leucine	5–6	8–10
DL-Phenylalanine*	3	5
L-Tryptophan	1–2	1–2†
DL-Methionine	2	3
L-Aspartate	8	10

* Concentration $M/30$ of L-isomer. † More than control.

It is interesting to note that the activities of the different amino-acids in transamination *in vitro* show a rather close correlation with their effectiveness in supporting growth of 'amination-deficient' mutant strains[3] which apparently lack glutamic dehydrogenase[5] and require exogenous α-amino-nitrogen for growth. Methionine, which is a relatively very effective amino donor for the intact mould, while being acted on only slowly by extracted transaminase, is the only striking exception.

Proteolytic Activity in Hen's Egg prior to Incubation

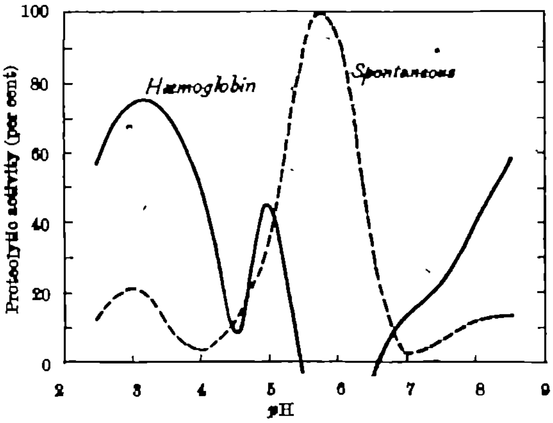
For this investigation, I used highly fertile eggs of pure breed (White Leghorn), laid in the afternoon. The eggs were stored at low temperature for a maximum of three days.

For chromatographic assay of free amino-acids, white and yolk were homogenized separately and extracted with alcohol in final concentration of 80 per cent. Two-dimensional chromatograms were run in (1) butanol – acetic acid – water and (2) phenol – water. The chromatograms were dried in an air current at approximately 50° C. and developed with ninhydrin. Munktell *OB* paper was used. For hydrolysis tests extracts were treated with 6 *N* hydrochloric acid for six hours. Chromatograms sprayed with basic copper carbonate gave no spots with ninhydrin. The results of chromatography are evident from the accompanying table.

Substance	R_F value in butanol–acetic acid–water	R_F value in phenol–water	Intensity of spots	Approx. conc. in yolk (mgm. per cent)
Peptide containing lysine	0·09	0 21	+	
Lysine*	0 07	0 35	+++	150
Aspartic acid	0·21	0·40	++	
Unknown*	0·23	0·34	+	
Arginine	0·13	0 45	+++	150
Glycine	0·22	0 45	+	
Glutamic acid	0·30	0·45	++	
Threonine	0·28	0·54	++	
Citrulline	0 20	0 64	+	
Alanine	0·34	0·58	+++	60
Unknown	0·22	0·81	+	
Tyrosine	0 46	0·64	+	
Valine	0 52	0 79	++	
Leucine	0·68	0·85	+++	100

* Obtained after hydrolysis.

The various amino-acids are all among those reported from yolk-protein[1]. In the white, there are no demonstrable free amino-acids; but in the yolk freed from the blastoderm the concentration is exceptionally high. Consequently, mobilization of amino-acids occurs in the yolk apparently independently of the embryo. For this reason it may be assumed that pre-formed proteolytic enzymes are active in the yolk.



pH-Activity of yolk proteinases in the hen's egg

For determination of this expected proteolytic activity, extracts of yolk freed from blastoderm were made with glycerol–water (30 per cent) and used immediately. As substrate undenatured hæmoglobin was used in 1 per cent solution. Merthiolate was added. Samples mixed with buffer solution (MacIlvaine's standard buffer) were incubated at 39° C. for 2 hr. The proteolysis was stopped by adding trichloracetic acid (5 per cent). Samples were examined in the spectrophotometer at 2750 A. for liberated cyclic amino-acids. Rectilineal curves were obtained for at least five hours. From the accompanying graph it is apparent that there are at least three proteinases in the yolk, acting at different pH's. The spontaneous activity around pH 6 is very high, and addition of hæmoglobin has apparently an inhibiting effect thereupon.

The work is being continued and further results will be published elsewhere.

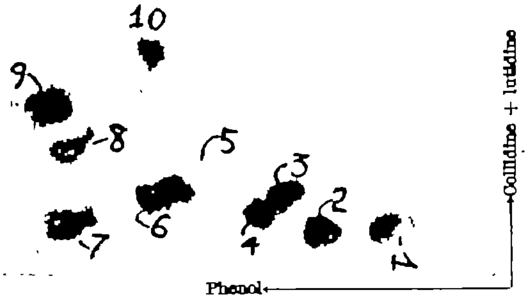
Chromatographic Analysis of Amino-acids of Molasses and other Beet-sugar Industry By-products

WE have applied chromatographic analysis to the detection of the amino-acids present in beet molasses and other by-products of the sugar-beet industry.

We used the descending paper-chromatography technique described by Consden, Gordon and Martin[1]; Whatman No. 1 paper, and the phenol, lutidine + collidine system were used. A 0·1 per cent solution of ninhydrin in butanol was used for detecting the spots.

Most of the chromatograms were obtained without any purification of exhausted molasses; in every run we used 5 mgm. of substance dissolved in distilled water (1 : 10 w/v). The chromatograms show nine spots well separated; after several trials we are able to attribute the spots to the following amino-acids: aspartic, glutamic, γ-aminobutyric, serine, glycine, alanine, valine, leucine, tyrosine. A good deal of pyrrolidone carboxylic acid is also present. This does not give a spot with ninhydrin; but the chromatograms made after treatment by acid hydrolysis of the molasses show a broader and more intense spot of glutamic acid. No traces of basic or sulphurated amino-acids were found. A detailed account of this work will be published elsewhere.

Applying a desalting procedure to the molasses solutions we obtained clearer chromatograms, with sharper spots. For this purpose we used a desalting apparatus analogous to that described by Consden, Gordon and Martin[2]. The chromatograms obtained in this way give, besides the nine spots already identified, another spot, much weaker than the others, due to threonine. The accompanying photograph is of a chromatogram obtained with desalted molasses.



(1) Aspartic acid, (2) glutamic acid, (3) serine, (4) glycine, (5) threonine, (6) alanine, (7) γ-aminobutyric acid, (8) valine, (9) leucine, (10) tyrosine

Regarding the quantity of amino-acids, in so far as the spots show, we can say that the most intense spot is that due to alanine; the γ-aminobutyric, glutamic and leucine spots follow in order of intensity. The spots due to aspartic acid, glycine, serine, valine and tyrosine are less intense.

We have found the same amino-acids in a sample of concentrated baryta-process waste liquors, and in different samples of first-run molasses.

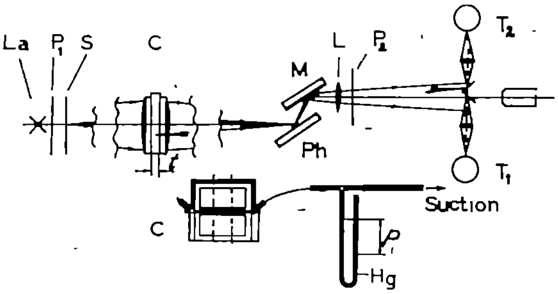
A Highly Sensitive Phase-Contrast Refractometer for Liquids and Gases

THE accompanying diagram shows the essential parts of a refractometer using the principle of phase contrast, which is new for this class of instrument. It gives relative measurements, like most of the applications of the Jamin and the Rayleigh refractometers depending on interference. The liquid or gas to be measured is enclosed in the central horizontal cell C about 1 mm. in height, the reference liquid or gas filling the upper and lower portions. The plane-parallel frame forming the middle of the cell, and made of glass, plastic or stainless steel with its plane sides lapped, is made tightly adherent to the two highly polished plano-convex lenses of selected homogeneity.



The optical system is symmetrical about this lens-like cell. An image of the entrance slit S, illuminated by monochromatic 5461 A. light from a mercury lamp, is formed by this cell on the central part of the phase mirror Ph. Then the light is passed, by means of the mirror M, through the lens L, which forms, in the plane dotted in the diagram, the phase-contrast image of the cell C. This image can be viewed by an eyepiece or a microscope. But in order to measure the intensity of a defined part of the image of the central cell, compared with the intensity of a second defined part of the image field, these two parts are projected on to the two photomultiplier tubes T_1 and T_2, respectively.

The phase mirror is based on the principle described by Françon and Nomarski[1] and modified by me[2]. To render the instrument uniformly sensitive over the whole region of measurement, it consists of several portions giving different phase-turning angles. Two 'Polaroids' P_1 and P_2 serve to determine and vary the vector origin.

According to the theory previously given[3,4], the difference of refractive index between the two liquids, $n_2 - n_1$, is determined by the intensity ratio between the two fields. This is a function of the path difference or, more exactly, of the phase difference angle $(n_2 - n_1)t.2\pi/\lambda$. It may be an arbitrary part of a complete turn, or several turns, but full details of the procedures cannot be given here, only mentioning that the number of whole turns is counted as the displacement of the zero order fringe from a double slit system as used in Young's experiment.

A very simple experiment is to make the optical path difference exactly one wave-length, that is, the phase angle exactly 2π, since it can be done visually by equalizing the intensities as in a Lummer–Brodhun photometer. The air of the central cell is pumped out, and the positions of the manometer corresponding to equal field intensities are noted. The difference of pressure equivalent to one wave-length was found to be 149 mm. of mercury; the thickness t being 10·4 mm. and the air temperature 22·4° C. This gives a refractive index of $2 \cdot 68 \times 10^{-4}$ for air of the same temperature and 760 mm. mercury pressure. When reduced to 20·0° C., the result is $2 \cdot 70 \times 10^{-4}$, which, considering the very simple means used for making the measurements, is in good accordance with the precision measurements of $2 \cdot 731 \times 10^{-4}$ [5].

In this Laboratory we measure photoelectrically with an accuracy of 0·5 per cent per amplitude in a phase-contrast field. As the vector is about unit length, the accuracy approximates to $0 \cdot 5 \times 10^{-2}/2\pi$ of a turn, or for the refractive index difference at $t = 10$ mm., which thickness contains 18,300 periods, the precision is 5×10^{-8}. This is more than ten times better than the results obtained by any interferometer[5]. An amount of at least 0·1 cm.^{3} of the liquid under examination is necessary and about 10 cm.^{3} of reference liquid. For a mixture of heavy and ordinary water, this means an accuracy of analysis of 0·001 mole per cent. Measurements have not yet been made on account of the lack of precise reference standards.

The precision can be reduced by making t smaller, and it can probably be raised by increasing it to some centimetres. This is possible with maintained focusing of the image, as the focal lengths must be rather long for other reasons. The temperature remains fairly well constant because the measuring cell is surrounded by the reference liquid and separated from it by thin walls.

I am now working with Mr. Lars Johansson, chemical engineer, to elaborate the apparatus for routine use.

Fly Reactions to Insecticidal Deposits: a New Test Technique

MOST laboratory methods for evaluating residual insecticides involve crowding a number of flies together in rather small containers. Such crowding stimulates activity, which may cause the flies to pick up abnormal amounts of insecticide. These conditions are unnatural, and while useful and reproducible results may be obtained, their relevance to field performance is doubtful.

We have found that the difficulties can be overcome by using a 'single fly' technique, based on the exposure in a large treatment cage of one fly at a time. Interference from other flies is avoided and fly behaviour can be studied in detail. Three-day-old well-fed female houseflies, which, if undisturbed, normally remain immobile on an untreated surface for three to five hours at 24–26° C., were used in all tests.

A cubical cage of 2-ft. side forms the container, and is about the minimum size in which a fly shows no reaction to confinement. The cage consists of a light wooden frame having a paper back as the treatment surface, the sides and top covered with mosquito netting, and the bottom open and resting on a table covered with clean paper. The fly is introduced by tilting the cage, allowed to settle, and induced by tapping the sides to come to rest on the treated surface. It is then left undisturbed and watched. When it leaves the surface, and when it is knocked down, the time is recorded; the fly is caught and placed in a separate small individual cage for subsequent observation. Before and after test the flies are fed on milk and kept at 24–26° C. It was found that minor changes in environment affected the results, hence comparative tests were run concurrently in adjacent cages.

The results obtained in a typical series of tests are summarized in the accompanying table, in which averages and standard deviations are given. The tests were made with a normal strain of *M. domestica* with unglazed wallpaper as the treatment surface; there were ten replicates.

Treatment	Resting period (min.). Average and standard deviation	Time to knock-down (min.) from beginning of resting period. Average and standard deviation	Mortality % after 24 hr.
DDT dispersible powder at 250 mgm. *pp'* isomer per sq. ft.	10±2·8	See below*	20
Crude BHC dispersible powder at 25 mgm. γ per sq. ft.	22±4·8	38±7·9	100
γ BHC dispersible powder at 25 mgm. γ per sq. ft.	29±3·2	35±4·8	100

* No knockdown in eight cases; knockdown in 3½ and 24 hr. for remaining two.

The results show that consistent treatment differences can be obtained with very few flies. The most striking observation is that the flies on BHC deposits do not leave the surface until they have acquired a lethal dose, whereas the flies on DDT deposits leave the surface much earlier, and mainly survive. Before leaving the surface, the DDT flies are obviously disturbed, as shown by the frequency of cleaning operations and erratic movements, whereas the BHC flies are comparatively quiescent. This abnormal behaviour of the DDT fly persists for about an hour after the surface is left. Many similar comparisons were made and gave the same results. At 100 mgm. of DDT per sq. ft. no knockdown or kill resulted in twenty-four hours from this single contact.

Preliminary tests with *Aedes aegypti* on similar lines have shown similar results on a much reduced time-scale, and further tests with this and *Anopheles* spp. are in hand.

It is felt that differences in behaviour of this kind must operate, to some degree, in the field and that, therefore, laboratory data obtained by this method can be of help in interpreting and predicting field results. The study of such differences in behaviour may throw light on the development of resistance by insects to certain chemicals.

Gravitation in Kinematic Relativity

A crucial test of a relativity theory of gravitation is its ability to explain (*a*) the perihelion advance of a planetary orbit as observed in the case of Mercury, and (*b*) the deflexion of light in a gravitational field as observed in the field of the sun. Another, completing the trio of tests which Einstein's general theory satisfied with such notable success, is in a different category, since it involves some hypothesis concerning the 'proper' frequencies of atomic vibrations; this is (*c*) the shift of the spectral lines emitted by atoms near a massive body, as observed in the case of light from the sun and from the companion to Sirius. It is not difficult to apply tests *a* and *b* to the gravitational part of Milne's theory[1], assuming that the equations of motion given by Milne hold in the field of the sun. The results are that, first, there is a perihelion motion, but it is in the wrong direction, and secondly, there is no gravitational deflexion of light. The failure under the first test could perhaps be accounted for by the fact that the sun is not at rest in the substratum; but if this were so, the perihelion effect would depend critically upon the sun's velocity relative to the substratum and upon the orientation of the planetary orbit under consideration. On the whole, it appears that Milne's dynamical theory does not compare favourably with Einstein's general theory.

This conclusion should not be regarded as reflecting on the whole of Milne's kinematic theory, for it has already been remarked[2] that Milne's system of dynamics is not an inevitable consequence of his fundamental principles, but is only one of a number of possible systems. A theoretical defect of Milne's system is that it does not satisfy a least action principle. This can be remedied by starting with a variational equation having the required Lorentz invariance; and one of the systems arising in this way, analytically the simplest, is particularly interesting because it leads to precisely the same perihelion motion and deflexion of light as given by general relativity. This system can be described briefly in terms of Newtonian space and time, the curvature of space-time being neglected since we are now concerned only with local effects.

Consider the variational equation

$$\delta \int \exp\,(-2\varphi/c^2)\,(c^2 + \mathbf{V}^2)\,dt = 0, \qquad (1)$$

where $\mathbf{V} = d\mathbf{r}/dt$ is the velocity vector, c is constant, and $\varphi(\mathbf{r})$ is the Newtonian potential function. This leads to equations of motion which can be written:

$$\frac{d}{dt}\left(\frac{\mathbf{V}}{1-\mathbf{V}^2/c^2}\right) + \frac{1+\mathbf{V}^2/c^2}{1-\mathbf{V}^2/c^2}\,\mathrm{grad}\,\varphi = 0, \qquad (2)$$

and an 'energy integral':

$$\varphi + c^2 \log\,(1 - \mathbf{V}^2/c^2)^{-1/2} = \text{constant}, \qquad (3)$$

giving the classical $\varphi + \frac{1}{2}\mathbf{V}^2 = \text{constant}$ when $c \to \infty$.

The scalar velocity of a test particle cannot exceed c, and a particle moving initially with speed c continues to move with this speed. Identifying such particles with light photons, it follows that their paths are given by the variational equation

$$\delta \int \exp\,(-2\varphi/c^2)\,ds = 0, \quad ds^2 = d\mathbf{r}^2. \qquad (4)$$

Thus light paths are the geodesics of a conformally flat 3-space.

Motions in the field of a massive particle M, for example the sun, are found by substituting $\varphi = -\gamma M/|r|$. It can be calculated from (2) that an orbit has an advancing perihelion, and from (4) that light is deflected towards the sun. In each case the formula is exactly the same as that given by general relativity[3].

An attempt to introduce the third Einstein test could be made by interpreting the variational equation (4) as giving least time in accordance with Fermat's principle; this would suggest that the frequency of an individual photon at any point of its path is proportional to $\exp(-2\varphi/c^2)$. In the case of light from a massive body the resulting spectral shift would be twice as large as that predicted by general relativity.

The simplicity of equation (1), with its success in giving at least two of the observed relativistic effects, suggests that it should be applied to material systems which are too complicated to be handled by the field equations of general relativity. It would be interesting to see if it leads to the prediction of any new observable relativity effects.

An Attempt to Measure the Annual Parallax or Proper Motion of Four Radio Stars

PREVIOUS attempts to measure the annual parallax of intense radio stars[1,2] have indicated that their distances exceed 1/50 parsec. These results were obtained by using an interferometer arrangement to determine the positions of individual stars over a period of many months. Observations of this type are limited[4] by inconstancy of the phase retardations in the transmission lines connected to the aerials of the interferometer. This source of error, which is analogous to the collimation error of a visual transit telescope, may, however, be largely eliminated if observations are made of the *relative* positions of a number of radio stars. The difference of the right ascensions of two stars of considerable angular separation should vary periodically as the earth goes round its orbit. It can be shown that a determination of the amplitude and phase of this periodic variation leads to a knowledge of the true parallax of each star separately. In addition, if no relative angular motion between a number of stars can be detected, it is unlikely that any of them has a proper motion greater than the accuracy of the observations.

The accuracy with which the difference of the right ascensions of two or more radio stars may be determined is very much greater than the absolute accuracy of the interferometer system, since th collimation error need only remain constant for th duration (a few hours) of the experiment. The mos serious remaining error is caused by ionospheri refraction near dawn and dusk, when the ionospher is not horizontally stratified. This produces deviation in apparent right ascension and affect observations of parallax but not of proper motion. Th magnitude of the error is greater at the longer wavelengths.

Two series of observations have been carried ou in an attempt to measure the annual parallax o proper motion of the four intense radio stars 05·01 12·01, 19·01, 23·01 [3]. The first series was made wit the large 3·7 m. interferometer[3], and has lasted fo one year. Accurate observations were made of th apparent right ascension of each star on about fou days each week. Such frequent observations wer necessary owing to the large number of occasion on which irregular ionospheric refraction prevente accurate measurements[4]. The second series consiste of similar observations on a wave-length of 1·4 m. these observations have been maintained twice week for four weeks in each of the periods shown i the accompanying table.

For each group of observations lasting two or fou days a value of the collimation error was found b taking the mean of the deviations of the recorde positions from a fixed position for each of the fou stars. The difference between the recorded deviation and this mean value was then taken as th apparent movement of the star. Allowance wa made for the effects of aberration, nutation an precession.

The observations on 3·7 m. wave-length clearl showed the dawn and dusk refraction mentione above; the angular movements due to this wer approximately ½ minute of arc. An analysis of thes results is being made which may give information o the magnitude of the horizontal gradient of electro density in the ionosphere throughout the day. N angular movements were observed which could no be ascribed to this cause, and the experiment show that there is no annual variation greater than minute of arc for any of the four stars.

DEVIATION IN SECONDS OF ARC OF MEAN POSITION OF EACH OF THE FOUR STARS. WAVE-LENGTH, 1·4 M.

Period 1951	05·01 (Taurus)	12·01 (Virgo)	19·01 (Cygnus)	23·01 (Cassiopeia)
Jan.–Feb.	0±7	0±12	0±5	0±3
April–May	−27±11	+7±7	−2±2	−3±4
July	−11±6	+22±15	−5±7	−4±2

The results of the series on 1·4 m. wave-length ar shown in the table. This series shows that there i probably no annual variation greater than 20 second of arc in the positions of 05·01 and 12·01, or 5 second of arc for 19·01 and 23·01. It may therefore be concluded that these four stars must be at distance greater than 1/20 parsec, and that 19·01 and 23·0 are more distant than 1/5 parsec; the absence o any detectable proper motion further suggest that they are probably at distances greater tha ½ parsec.

This work was carried out as part of a programm of radio research at the Cavendish Laboratory, supported by the Department of Scientific and Industri Research. Thanks are due to Mr. B. Elsmore fo help with the observations, and to Mrs. A. C. Hollis

:allett, who analysed a large proportion of the :eoords.

Effect of a Magnetic Field on the Propagation of Sound Waves in a Ferromagnetic Material

EXPERIMENTS in progress on the propagation of igh-frequency longitudinal acoustic waves along a od of ferromagnetic material have shown such waves o be influenced by the application of an external nagnetic field in two ways. First, the velocity of ropagation is modified, as is to be expected from the o-called ΔE effect in magnetostriction experiments, hich refers to the change of Young's modulus with he applied magnetic field, and is of the order of a w per cent. Secondly, the attenuation of the waves s in general reduced as the applied field is increased, hus confirming the observations briefly noted by . F. Rogers and S. J. Johnson[1].

In the present work, both transerse and longitudinal magnetic ields have been employed, and the ffects are similar, in each case howing a decrease of attenuation owards a minimum value as the nagnetization approaches saturaion (see Fig. 1). μ is the attenuaion coefficient defined by $\alpha =$ $_{0}$ exp $(-\mu x)$, where α is the pulse mplitude corresponding to the ath-length x.

The experimental arrangement s essentially that shown in Fig. 2. ulses of variable frequency and ength are generated and fed to an X-cut quartz ransducer, which acts as the transmitter and reeiver of the sound waves, and is placed in close conact with the material under test. A film of oil is sed as a coupling medium between the quartz and he material. The received signals are displayed on a cathode-ray oscillograph and typical records are shown in Fig. 3, the operating frequency being 2·5 Mc./s., and the materials refer to nickel and nickel–iron. The magnitude of the attenuation effect varies considerably with the material as indicated in Fig. 1.

The curve in Fig. 4 is derived from the direct observations by plotting $(\mu_0 - \mu_H)$ against the appropriate field-strength H, and it is evident that this form of presentation shows a striking similarity to the I–H initial curves of magnetization of a ferromagnetic material (I being the intensity of magnetization).

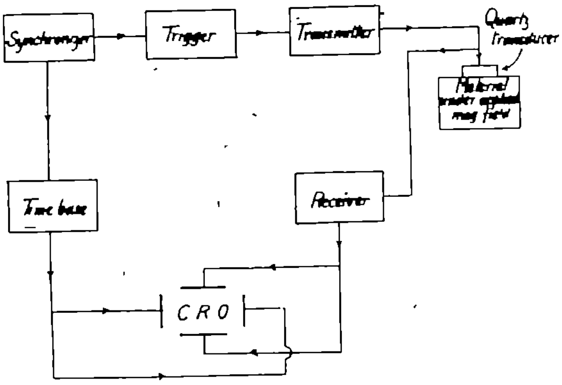

Fig. 2. Block diagram of experimental arrangement

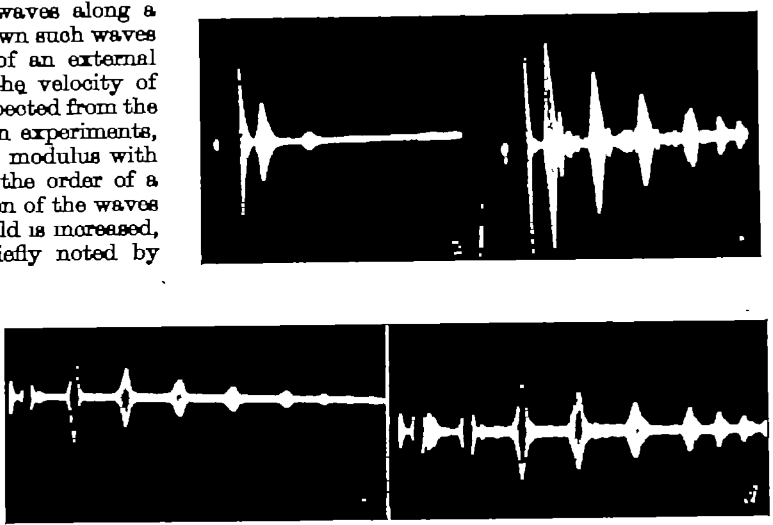

Fig. 3. Longitudinal waves in nickel - iron with: (a) zero applied magnetic field; (b) longitudinal applied magnetic field of strength 1,000 oersteds approximately. Longitudinal waves in nickel with: (c) zero applied magnetic field; (d) transverse applied magnetic field of strength 1,000 oersteds approximately

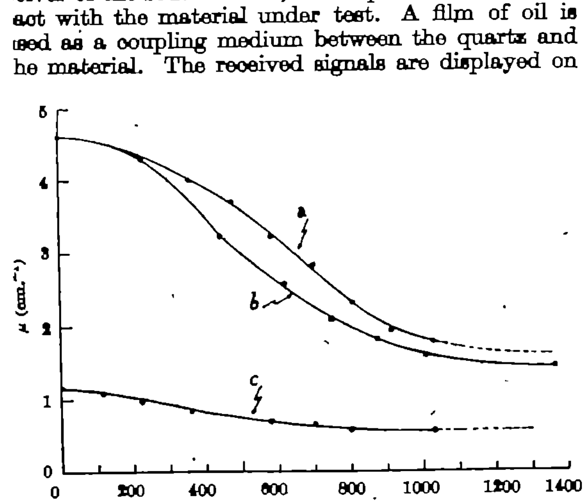

Fig. 1. Curve a, transverse field (nickel - iron); curve b, longitudinal field (nickel - iron); curve c, transverse field (nickel)

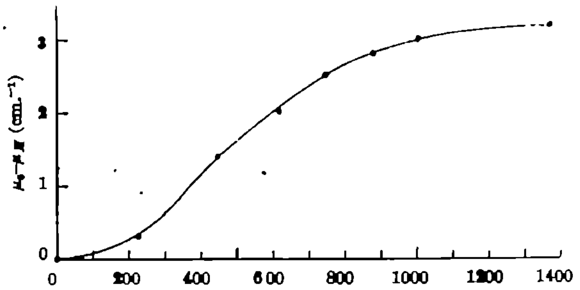

Fig. 4. Derived from Fig. 1 (b)

These results are a preliminary account of comprehensive investigations at present being undertaken with respect to type of wave, range of materials, magnetic field-strength and frequency of the pulse. Velocity measurements are also being correlated with the observations on attenuation.

Thanks are due to Sir George Thomson for providing facilities for this work in the Physics Department of the Imperial College.

A New Surface Viscometer

Of the methods which have been used to measure the viscosity of surface films on a liquid substrate only one, the canal or surface-slit method, is amenable to rigorous mathematical treatment. Harkins and Kirkwood[1] derived an equation which could be applied to this method provided that certain modifications could be made to the apparatus as used by Joly[2]. To measure the viscosity of dilute soluble films (to which the surface-slit method cannot be applied), a new method has been developed which is capable of rigorous interpretation.

The substrate (water or solution) is made to flow at a constant volume rate, V, through a horizontal channel of rectangular cross-section which it fills completely. The velocity, v_m, of an element of the surface along the centre of the channel may be measured by observing the passage of a floating particle of graphite between marked positions.

So long as there is no surface-pressure gradient, the flow velocity, v, satisfies, besides the Navier–Stokes equation, the boundary condition in the surface ($z = 0$):

$$\mu \partial^2 v/\partial x^2 + \eta \partial v/\partial z = 0,$$

where the distance, x, is measured across the channel and z vertically downward. For a channel of width a and depth b and a very small hydrostatic pressure gradient, A, in the direction of flow we find:

$$v_m = \frac{4Aa^3}{\pi^3} \Sigma' \sin \frac{n\pi}{2} \frac{\tanh (n\pi b/2a)}{n^3 a\eta \coth (n\pi b/a) + n^4 \pi\mu} \quad (1)$$

and

$$V = \frac{Aba^3}{12\eta} - \frac{8Aa^4}{\eta\pi^5} \Sigma' \frac{a\eta + 2n\pi\mu \tanh(n\pi b/2a)}{n^5 a\eta + n^6 \pi\mu \coth (n\pi b/2a)}, \quad (2)$$

where the sum is to be taken over all odd values of n. The ratio v_m/V is independent of A, and for $b > 3a$ simplifies to:

$$\frac{v_m}{V} = \frac{48 \Sigma' (-1)^{(n-1)/2} \dfrac{1}{n^3 + n^4 \pi\mu/a\eta}}{\pi^3 ab - \dfrac{96a^2}{\pi^2} \Sigma' \dfrac{1}{n^5} \dfrac{a\eta + 2n\pi\mu}{a\eta + n\pi\mu}} \quad (3)$$

The only unknown in this equation is μ; for given values of a, b and η, it is a simple matter to plot the ratio v_m/V against μ. The measurement of v_m, to give less than 5 per cent error, must be confined to particles floating along the central 20 per cent of the channel surface.

To illustrate the sensitivity of the method, for $a = 0{\cdot}153$ cm., $b = 0{\cdot}60$ cm., and $\eta = 0{\cdot}01$ poise, the following table shows values of v_m/V corresponding to a range of values of μ:

$\mu \times 10^4$ (surface poise)	0	0·5	1	2	5	10	20
v_m/V	17·8	16·8	15·1	13·1	9·3	6·3	3·

An experimental difficulty occurs in measuring the surface viscosity of some surface-active solutions. A negative surface-pressure gradient is set up along the channel, tending to retard the surface flow. If a barrier is placed across the surface of the channel before commencing the bulk flow, the surface pressures at the ends of the channel may be kept the same. When the flow has reached a steady state, the barrier is lifted and measurements of v_m are made after measured intervals. The value of v_m for zero surface-pressure gradient is then obtained by extrapolation. The form of the v_m versus time curve, and the difficulty of obtaining measurements at short intervals after lifting the barrier, sometimes makes this method impracticable and recourse is being made to a second method. After a period, v_m approaches a constant value, apparently indicating that a steady state with a constant surface-pressure gradient has been set up. By making further assumptions it is possible to make allowance for this back pressure (a measurable quantity) and to calculate the surface viscosity from the steady-state flow.

It must be assumed, with Harkins and Kirkwood[1], that the surface film is incompressible, that surface viscosity is independent of surface pressure and that there is no slip between surface film and substrate. Equations for v_m and V, obtained in the same way as the Harkins and Kirkwood equation in terms of a surface-pressure drop B, may be superposed linearly on the equations (1) and (2) to give equations for the flow when both hydrostatic and surface-pressure gradients are operative. The hydrostatic pressure gradient, A, is again eliminated between these equations to obtain an equation of the form:

$$VK_1 + BK_2 - v_m K_3 = 0,$$

where K_1, K_2 and K_3 are analytical functions of μ, η, a and b. By plotting v_m/V against μ, a family of curves is obtained for various values of B/V.

Where the surface film is moderately close packed, for example, in condensed insoluble films and in concentrated soluble films, a back pressure develops so rapidly that extrapolation to zero back pressure is impossible and v_m becomes so small that accurate determination of its steady value becomes impracticable. This constitutes a major limitation on our method of measuring surface viscosity. For dilute gaseous films, soluble or insoluble, the method appears most promising.

A more complete description of the experimental methods and the mathematical treatment will be published later.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, December 3

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. W. S. Feldberg, F.R.S.: "Acetylcholine and the Central Nervous System".*

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. R. H. Gray: "Some Aspects of Industrial Filtration".

Society of Chemical Industry, London Section (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. W. A. M. Edwards: "The Sulphuric Acid Industry—Changing Raw Materials and Processes".

South-East London Technical College (at Lewisham Way, London, S.E.4), at 7 p.m.—Mr. W. Stern: "The Production of Sapphire Bearings".

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Mr. C. H. Hampshire: "The International Pharmacopoeia".

Tuesday, December 4

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. Matthews, Mr. H. F. Goodman and Mr. G. H. Botham: "The Design of Process Equipment with special Hygienic Requirements".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "The Servicing of Electrical Instruments in Large Industrial Undertakings" (to be opened by Mr. A. J. Young); Discussion on "The Maintenance of Electrical Instruments in Atomic Energy Factories" (to be opened by Dr. Denis Taylor).

Society of Chemical Industry, Crop Protection Panel of the Agriculture Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. W. H. Read: "Chemical Control of Glass-house Pests and Diseases".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. L. J. Witts: "The Scientific Basis of Medicine, 17, The Rate and Materials of Blood Formation".* (Further Lectures on December 6 and 11.)

Society of Chemical Industry, Microbiological Group (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 6.15 p.m.—Dr. M. Horwood: "Industrial Microbial Enzymes".

Wednesday, December 5

Joint Committee on Materials and their Testing and the Institute of Welding (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 10 a.m.—Symposium on "Recent Developments in the Notch Bar Testing of Materials and their Relation to Welded Construction".

Physical Society, Colour Group (in the Lecture Theatre, Victoria and Albert Museum, South Kensington, London, S.W.7), at 2.30 p.m.—Dr. H. Ruhemann: "Great Painters' Techniques and Colour Reproduction".

Aslib (at the British Council Film Theatre, 6 Hanover Street, London, W.1), at 5.30 p.m.—Mr. Bernard Chibnall: "Shell Film Unit Stock Shot Library".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. P. E. Axon: "An Investigation into the Mechanism of Magnetic-Tape Recording".

Royal Meteorological Society (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. J. Paton: "The Optical Properties of the Atmosphere". (Sixth-form Scholars are invited to attend.)

Society of Chemical Industry, Food Group (joint meeting with the Society of Public Analysts and Other Analytical Chemists, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Discussion on "The Food Standards Issue—What does the Future Hold?".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "Science in the Mountains" (Speakers: Dr. M. F. Perutz, Dr. E. P. George and Dr. B. H. C. Matthews, F.R.S.).

British Psychological Society (in the Psychology Department, University College, Gower Street, London, W.C.1), at 8.15 p.m.—Prof. T. M. Newcomb: "Some Contemporary Developments in Social-psychological Research".

Thursday, December 6

University of London (at the Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E.5), at 3 p.m.—Prof. J. Z. Young, F.R.S.: "The Anatomy of Learning".*

Physical Society, Low-Temperature Group (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 5 p.m.—Sixth Annual General Meeting; at 5.15 p.m.—Mr. B. Blay and Mr. K. W. Glover: "The Measurement of Flow and Level of Liquefied Gases".

British Glaciological Society (at University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. F. Nye: "The Mechanics of Glacier Flow".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. H. L. Haslegrave: "Technical Colleges and Education for the Electrical Industry".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. L. J. Witts "The Scientific Basis of Medicine, 18, Alimentary Factors in Blood Formation".* (Further Lecture on December 11.)

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. P. B. Medawar, F.R.S.: "Some Unsolved Problems of Biology".*

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. J. Seddon "Air Intakes for Gas Turbines".

College of Preceptors (at 2 Bloomsbury Square, London, W.C.1), at 6 p.m.—Mr. Geoffrey Gorer: "The Limitations of National Thinking and Feeling" ("Horizons in the School", 1) (Joseph Payne Memorial Lectures).*

Society of Chemical Industry, Bristol Section of the Chemical Engineering Group (in the Chemical Department, The University, Woodland Road, Bristol), at 6.30 p.m.—Mr. K. Sharples and Mr. F. G. Shepstone: "Chemical Engineering Applied to the Fertilizer Industry".

Television Society (at the Cinematograph Exhibitors' Association, 164 Shaftesbury Avenue, London, W.C.2), at 7 p.m.—Mr. Bryan R. Overton: "Television Receiver Design for British and European Systems—a Comparative Study".

Friday, December 7

Royal Meteorological Society, Scottish Centre (in the Department of Natural Philosophy, The University, Drummond Street, Edinburgh), at 5.15 p.m.—Dr. R. C. Sutcliffe: "The Use of Upper-Air Contour Charts in Forecasting".

Institution of Mechanical Engineers (joint meeting with the Industrial Administration and Engineering Production Group, at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. C. H. Bradbury. "The Measurement and Interpretation of Machinery Noise with Special Reference to Oil Engines"

Society of Chemical Industry, London Section (joint meeting with the London Group of the Industrial Applications Section of the Royal Statistical Society, at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Mr. G. E. P. Box: "The Planning of Experiments in the Chemical Industry".

North-East Coast Institution of Engineers and Shipbuilders (at the Mining Institute, Newcastle-upon-Tyne), at 6.15 p.m.—Dr. W. S. Patterson: "External Ship Corrosion due to Bacterial Action".

Society of Chemical Industry, Manchester Section (joint meeting with the Local Sections of the Chemical Society and the Royal Institute of Chemistry, at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Sir Ben Lockspeiser, F.R.S.: "Scientific Problems in the D.S.I.R.".

Saturday, December 8

British Mycological Society (at the Linnean Society of London, Burlington House, Piccadilly, London, W.1), at 12 noon.—Annual General Meeting; at 2.30 p.m.—Dr. Lilian E. Hawker. "The Physiology of Myxomycetes" (Lister Memorial Lecture).

British Psychological Society (in the Eugenics Theatre, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Prof. C. A. Mace. "Education for Management in the United States—a Psychologist's Impression".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant (Grade A) in Physics and Physical Chemistry, and an Assistant (Grade A) in Mechanical Engineering, at the Birkenhead Technical College—The Director of Education, 63 Hamilton Square, Birkenhead (December 8).

Head of the Pure and Applied Science Department (with good academic qualifications in physical chemistry, and experience in teaching to B.Sc. and A.R.I.C. standard)—The Principal, Mining and Technical College, Church Street, Barnsley (December 8).

Lecturer in Physical and Inorganic Chemistry at the Rutherford College of Technology—The Director of Education, City Education Office, Northumberland Road, Newcastle-upon-Tyne 1 (December 8).

Statisticians (with honours degree in mathematics and training or experience in statistics) to initiate and take charge of the Centre, under the supervision of the Honorary Director—duties will be (*a*) the collation of world data on blood groups in relation to anthropology, including their analysis, and (*b*) the anthropological analysis of blood records of Great Britain—The Hon. Director, Nuffield Blood Group Centre of the Royal Anthropological Institute, 21 Bedford Square, London, W.C.1 (December 8).

Lecturer in Mathematical Physics—The Secretary, The University, Edgbaston, Birmingham 3 (December 10).

Lecturer in Public Health—The Secretary, The University, Aberdeen (December 10).

Lecturer in Oral Anatomy and Histology, combined with preventive dentistry, and a Demonstrator and Research Assistant in Dental and Oral Pathology—The Registrar, The University, Sheffield (December 15).

Scientist III (with an honours degree in science, preferably in chemistry and physics, or an equivalent qualification) in the Records Section of the Scientific Department at London headquarters, to assist in the collection and interpretation of scientific data and to prepare information reports—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/399 (December 18).

Meteorological Officers (6) in the Department of Industry and Commerce, Dublin—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (December 21).

CHIEF COAL SURVEY OFFICER (with high academic scientific qualifications; sound all-round knowledge of fuel technology and some research experience are desirable) in the Scottish Division—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, endorsed TT/403 (December 22).

SITE SUPERINTENDENT, a DEPUTY SITE SUPERINTENDENT, EXPERIMENTAL OFFICERS, and ASSISTANT EXPERIMENTAL OFFICERS by the **MINISTRY OF FUEL AND POWER** for experiments in underground gasification—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting F.862/51A (December 22).

ANIMAL HUSBANDRY OFFICER—The Secretary, Southern Rhodesia Government, 429 Strand, London, W.C.2 (December 24).

CIVIL ENGINEERS, SANITARY ENGINEERS, and STRUCTURAL ENGINEERS (all with the appropriate professional qualifications and experience) in a number of Departments in England and Wales—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. 3405.LA (December 31).

READER IN THE DEPARTMENT OF GEOGRAPHY IN THE RESEARCH SCHOOL OF PACIFIC STUDIES—The Administrative Officer in the United Kingdom, Australian National University, 27 Russell Square, London, W.C.1 (December 31).

SENIOR LECTURER, and a LECTURER, IN CIVIL ENGINEERING, at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 31).

SENIOR LECTURER IN VETERINARY PATHOLOGY AT THE UNIVERSITY OF QUEENSLAND—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 5).

SCIENTISTS II or III (Ref. TT/400) (with honours degree in electrical engineering or physics, with good knowledge of electronic techniques) in the telecommunications and light electrical engineering fields, and **ELECTRONIC ENGINEERS** (Ref. TT/401) to design and construct electronic devices for research, at the Central Research Establishment, Stoke Orchard, Cheltenham—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting the appropriate Ref. No. (January 12).

SENIOR LECTURER IN GENERAL BACTERIOLOGY at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 14).

AERONAUTICAL AND MECHANICAL ENGINEERS (Principal Scientific Officer grade) in the Structures Department of the Royal Aircraft Establishment, Farnborough, for work on the design approval of aircraft structures or on the solution of airworthiness problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting C.684/51A.

ELECTRICAL ENGINEERS AND PHYSICISTS AT THE ROYAL AIRCRAFT ESTABLISHMENT, South Farnborough: **PRINCIPAL SCIENTIFIC OFFICER** (Ref. D.501/51A) to act as Deputy Leader of a team engaged on the research and development of novel applications of radio techniques, **SENIOR SCIENTIFIC OFFICER** and **SCIENTIFIC OFFICER** (Ref. A.345/51A) to assist in various aspects of the work detailed above; **SENIOR SCIENTIFIC OFFICER** (Ref. A.346/51A) to work on novel forms of sighting equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

ELECTRICAL ENGINEERS and PHYSICISTS (Scientific Officer grade) in the Instrument and Photographic Department of the Royal Aircraft Establishment, Farnborough: (Ref. A.347/51A) for the assessment of analogue computor and servomechanism techniques and the development of precision equipment in that field for use in aircraft; (Ref. A.348/51A) for the analysis of the complex dynamical problems arising in automatic control of aircraft and for research upon methods of control; (Ref. A.349/51A) for research and development work in connexion with gyroscopic and allied instruments, (Ref. A.350/51A) for the development of aircraft cameras, involving image movement compensation, exposure frequency control and gyroscopic stabilization—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

ENGINEERS by the **MINISTRY OF SUPPLY** in London: (Ref. C.690/51A) for the production planning of chemical and mechanical propulsion units (rocket motors, pulse jet engines, etc.), ancillary equipments (fuel and booster pumps, mixing and pressure valves, igniters, etc.); (Ref. C.691/51A) for the production planning of guidance equipment (electronic, air and ground guidance apparatus, valves, fuses, test gear) and control equipment (mainly gyroscopic and servo-mechanisms) for guided weapons—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

HEAD OF THE DEPARTMENT OF POWER ENGINEERING AND ELECTRICAL TECHNOLOGY, Indian Institute of Science, Bangalore, India—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting D.485/510A.

HEAD OF THE MECHANICAL ENGINEERING DEPARTMENT, Wolverhampton and Staffordshire Technical College—The Clerk to the Joint Education Committee, Education Offices, North Street, Wolverhampton.

HONOURS GRADUATES IN PHYSICS or **CHEMISTRY**, for research work in connexion with the pottery industry—The Director of Research, British Ceramic Research Association, Queens Road, Penkhull, Stoke-on-Trent.

INSPECTOR OF HORTICULTURE (with a university degree or diploma in horticulture and/or Kew certificate) in the Ministry of Agriculture, Sudan—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Inspector of Horticulture 4/217'.

INSPECTORS (2) **OF MINES**, Tanganyika—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27099/5/51.

JUNIOR LECTURER (with an honours degree in chemistry) to assist with the teaching work of the **DEPARTMENT OF CHEMISTRY**—The School Secretary, Middlesex Hospital Medical School, London, W.1.

MECHANICAL ENGINEER (with A.M.I.Mech.E. or a degree in mechanical engineering), Northern Rhodesia, to assist the Senior Mechanical Engineer in administration of the Government's Mechanical Workshop Organization—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27835/8.

PHYSICISTS and **ELECTRICAL ENGINEERS** (Experimental Officer grade) in the Instrument and Photographic Department of the Royal Aircraft Establishment, Farnborough, for (*a*) development work on analogue computors and servomechanisms, (*b*) development of automatic pilots and associated equipment, and (*c*) research and development work in connexion with gyroscopic and allied instruments—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting A.352/51A.

PHYSICISTS and ELECTRICAL ENGINEERS (Scientific Officer grade) at a Ministry of Supply research establishment in the south-east of London: **ELECTRICAL ENGINEER** (Ref. D.490/51A) with a sound knowledge of physical principles and electronic applications to physics problems, a **PHYSICIST** or **ELECTRICAL ENGINEER** (Ref. A.337/51A) with experience in radio communications, a **PHYSICIST** (Ref. A.337/51A) with experience in electronic circuitry problems, for measurement of high-speed transients, an **ELECTRICAL ENGINEER** (Ref. D.490/51A) for research and development in V.H.F. and U.H.F. transmission and reception, and an **ELECTRICAL ENGINEER** (Ref. D.490/51A) for design and development work in a wide field of electronic instruments—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

PRE- AND POST-DOCTORAL RESEARCH and combined research and teaching positions in the fields of Colloid, Inorganic, Organic, and Physical Chemistry—Prof. R. D. Vold, Department of Chemistry, University of Southern California, Los Angeles 7, Calif., U.S.A. (apply by air mail).

RESEARCH METALLURGISTS (graduates) for work in the Tinplate Section—The Director, Tin Research Institute, Fraser Road, Greenford, Middx.

SENIOR LECTURER IN MATHEMATICS, a SENIOR LECTURER IN CHEMISTRY, a SENIOR LECTURER IN PHYSICS, and a SENIOR LECTURER IN TELECOMMUNICATIONS ENGINEERING—The Clerk, Northern Polytechnic, Holloway, London, N.7.

SENIOR LECTURER IN PHYSICS, a LECTURER IN PHYSICS, a LECTURER IN ZOOLOGY AND PHYSIOLOGY, an ASSISTANT (Grade B) **IN CHEMISTRY**, and an **ASSISTANT** (Grade A) **IN MATHEMATICS**—The Principal, West Ham Municipal College, Romford Road, London, E.15.

SENIOR LECTURER, and a LECTURER, IN THE DEPARTMENT OF CHEMISTRY AND APPLIED CHEMISTRY—The Principal, Royal Technical College, Salford 5.

SENIOR SCIENTIFIC OFFICER or **SCIENTIFIC OFFICER** in the **MECHANICAL ENGINEERING DEPARTMENT** of the Royal Aircraft Establishment, Farnborough: (Ref. C.685/51A) for research into the more fundamental aspects of the development of aircraft hydraulics, pneumatics and oxygen systems involving problems of gas and liquid flow, control systems and storage, (Ref. C.686/51A) for work on research aspects of aircraft vulnerability and weapon lethality, including field trials on representative aircraft parts, studies of new aircraft and weapons and statistical analysis of test results; **SENIOR EXPERIMENTAL OFFICER** and **EXPERIMENTAL OFFICER** (Ref. C.687/51A) to work on air crew oxygen breathing equipment which requires a knowledge of light precision engineering and a capacity for experimental and development work on components such as capsule and diaphragm operated mechanisms, reducing valves, etc. **EXPERIMENTAL OFFICER**: (Ref. C.688/51A) to assist with general laboratory and flight work on light mechanisms, cabin conditioning, hydraulic and pneumatic systems—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

SENIOR SCIENTIFIC OFFICERS or **SCIENTIFIC OFFICERS IN THE STRUCTURES DIVISION** of the Royal Aircraft Establishment, Farnborough: (Ref. C.707/51A) for theoretical work on aircraft flutter as affecting aircraft design, (Ref. C.708/51A) for investigation of problems connected with the specification of basic conditions for aircraft structural design, (Ref. C.709/51A) for investigation of dynamic problems as affecting aircraft structure, (Ref. C.710/51A) to assist with the design approval of aircraft structures and aircraft structural components—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

PLANNING THE LAND OF BRITAIN

THE title of the Ministry in which Mr. Harold Macmillan has succeeded Dr. H. Dalton has been changed from 'Local Government and Planning' to 'Housing and Local Government'. The word 'planning' thus disappears from ministerial titles for the first time since it was added to that of the Ministry of Works in 1942. It has not, however, been suggested that the fresh emphasis now placed on the housing responsibilities of Mr. Macmillan's office implies any shedding of responsibilities for the planning of the use of land from a national point of view, or that the National Parks Commission will no longer be responsible to him.

Planning responsibilities in Great Britain are likely to be increasingly onerous in the immediate future, and though to some extent the requirements of housing and town-planning for land may place Mr. Macmillan in an invidious position in co-ordinating rival claims for the use of land, it can be safely assumed that such functions will be discharged with good sense and imagination. Long-term national interests, which, as *Planning* has rightly insisted in a recent broadsheet on "Land-Use Planning", are the decisive element in such planning, will undoubtedly suffer if Mr. Macmillan's co-ordinating powers are no wider than those of his predecessor, and if they are not exercised with vision and energy as well as tact. Claims for the use of land in the national emergency are no less acute and conflicting than at any time during the past two decades, and unless wisely and firmly resolved may do irreparable damage to long term interests, especially in respect of those amenities which the National Parks and Access to the Countryside Act is intended to safeguard.

Mr. Macmillan, moreover, has taken office at a time when Dr. Dalton's handling of the question of administration of the proposed parks had engendered profound scepticism as to whether any really national parks would be established. Designation orders for four of the proposed parks were signed during Dr. Dalton's term of office, and the boundaries of the Peak District, the Lake District and the Snowdonia National Parks were confirmed by him. The order designating the Dartmoor National Park has since been confirmed by Mr. Macmillan. The route for the Pennine Way was also approved by Dr. Dalton, and this fine project should now go to fruition with little need for personal attention from the new Minister, who will, however, be expected to watch over it benevolently, since in the austere conditions which the nation is called upon to face, access to the countryside may play a vital part in maintaining health and morale.

The situation as regards the national parks is otherwise, and for all the vigour with which the initial task was tackled by Dr. Dalton and the National Parks Commission, a situation has developed which threatens to frustrate the whole purpose of the Act unless the question of joint planning is firmly and promptly handled in accordance with the pledges given in Parliament when the Bill was passed. Some disappointment has been expressed in regard to the national members appointed by the Minister to the Joint Boards for the Peak District and Lake District National Parks, on the ground that insufficient use has been made of the services of those known to possess experience, knowledge and vigour in local rural preservation; but that disappointment may not in the event prove justified, and is entirely secondary to that of the financial independence of the Joint Boards.

When, at the committee stage of the Bill, an amendment was moved which would have ensured that the finance committees of county councils whose powers were being transferred to a joint board should have no control over the board, the Minister, then Mr. Silkin, immediately stated that, once an 'order' had been made to set up a joint planning board, there would be no need to go back to the separate authorities for permission to arrange the necessary finance. It would be met entirely by precept issued on the counties by the board. The first schedule of the 1949 Planning Act specifically provides for this, and it was on this undertaking that the amendment was withdrawn. In spite of this pledge, in his 'order' establishing the Lake District Joint Planning Board, Dr. Dalton placed a limit of £7,500 on the annual expenditure of the Board, and made any increase in this figure subject in the first instance to the consent of the three county councils in the areas of which the Park lies. This figure, which is half that originally suggested as probable by the Ministry of Local Government and Planning itself, is the figure at which the county councils offered to do the work with their own officers. The order thus frustrates the freedom of the Board as regards planning, which was expressly promised in the House of Commons, together with financial independence. It is understood that the National Parks Commission has already protested to the Minister that it considers the councils' proposals to be unsatisfactory and that in its opinion the Lake District Joint Board should appoint its own planning officer, who should be wholly in its service. It is, of course, a statutory duty of the commissioners, under the National Parks Act, to advise the Minister "generally and in relation to particular national parks" as to the action needed to be taken. By the terms of the Act, too, the Commission should be consulted about such administrative matters; but this obligation seems to have been disregarded: the arrangements appear to have been concerted entirely between the Ministry and the county councils.

There is also controversy over the Joint Board for the Snowdonia National Park, where the Caernarvon County Council has been pressing for administration, in defiance of the Act, by a joint advisory committee.

This situation demands early attention and action from the new Minister. The present Government is not bound by the pledges of its predecessor when the Bill was debated in Parliament, although the division was not on party lines. The principle at stake, however, is so vital that if the nation cannot afford at present the small sums necessary to secure effectiv national administration of the parks, the better cours would be to repeal the National Parks Act an dissolve the National Parks Commission. That a least would be an honest policy, and would not delud the nation into thinking it was enjoying somethin which can never be achieved under local authorit administration.

There are, of course, immediate considerations t be weighed before taking such drastic action, quit apart from the reproach which future generatior would rightly level at us for the irreparable loss t amenity as well as to scientific interests. As ha been urged before in these columns, our scen heritage represents a spiritual asset, which may b of great value in our struggle for economic recover Access to the countryside and national parks ma yet prove an important factor in sustaining th health and spirit of the people, and the case fo nature reserves rests in part on their contributio to the more effective use of the natural resources o Great Britain through a fuller scientific knowledg of the fauna, flora and ecology.

These considerations must be weighed by th Government, and it is to be hoped that there wi be no hesitancy in dealing with the situation whic Dr. Dalton's dubious administration has encourage Let there be either repeal of the National Parks A with a straightforward statement as to why th nation cannot afford the sums required to administ the parks, or firm administration of the Act i accordance with the terms laid down and the unde takings given in Parliament. County counci cannot be relied on to formulate and pursue national policy—and indeed it is unfair to expe it of them. Their co-operation and local advi are none the less essential, and without them th national parks will not be fully effective. Th devising and implementing of a national polic however, belongs to another sphere, and confusio and frustration are liable to result if the two a mixed.

SCIENCE AND RELIGION

Natural Science and the Spiritual Life

Being the Philosophical Discourse delivered befo the British Association for the Advancement Science at Edinburgh on 12 August 1951. By th Rev. John Baillie. Pp. 44. (London, New York an Toronto: Oxford University Press, 1951.) 5s. ne

THE Philosophical Discourse delivered before th British Association at Edinburgh this year h one distinction which has not always been possess by such compositions—it is really philosophical. deals with a subject which is both relevant to t concerns of the British Association and of fund mental importance—the relation between science a religion. Those who know Dr. J. Baillie's writin will expect to find learning and literary grace happ wedded, and they will not be disappointed. "C two walk together except they be agreed ?" is t text of the discourse; but there is a subsidiary te from the Phædo, in which Socrates recalls his early nterest in natural science and the reasons which led him to abandon these studies. The thesis which Dr. Baillie develops and defends is that there is no inherent conflict between religion and science; but they cannot be brought into a harmonious relation by assigning one field of our experience to science and another to religion. "Nowhere is it possible to draw an iron curtain across the field of our experience and proclaim either the exclusion of science from the one side or its totalitarian right on the other. What we have to do with is rather two diverse ways in which the whole territory of our human experience may be approached and explored."

The thesis is elaborated by a rapid but illuminating survey of later Western thought from the point of view of the two types of causation, 'efficient' and final'. We cannot follow the argument in detail here. No doubt it will raise questions in many readers' minds, as the author intended. Two may be mentioned. It is not quite clear whether Dr. Baillie would draw a distinction between religion and theology and, if so, how he would define it. This is mportant, for the conflicts between religion and science have for the most part been, in fact, between theological doctrines and scientific theories. One can magine, indeed one knows, scientific men who claim to have a religious approach to experience but reject the theological propositions which are presented by Christianity or any other religion for their belief. Dr. Baillie, again, has much which is most interesting to say on the Christian origins of natural science. He holds, with many other eminent philosophers and historians, that but for Christianity there would have been no science. I think we must agree that the Christian world-view did, in fact, prepare the way for the scientific method by its destruction of the ancient cyclic conception of existence and that its doctrine of God had something to do with the evolution of the ideas of the uniformity of Nature and natural aw; but I find it difficult to believe that apart from Christianity the Western mind would never have hit upon the plan of investigating Nature by observation and experiment. After all, many of the presuppositions of natural science are present in Lucretius. But I have Whitehead, Berdayev, Ritchie and Foster, as well as Dr. Baillie against me. Dr. Baillie has written a stimulating pamphlet which deserves to be pondered and discussed.

W. R. MATTHEWS

GLASGOW CHEMISTS

An Eighteenth Century Lectureship in Chemistry
Essays and Bicentenary Addresses relating to the Chemistry Department (1747) of Glasgow University (1451). Edited by Dr. Andrew Kent. (Glasgow University Publications, 82.) Pp. xv+233+19 plates. (Glasgow: Jackson, Son and Co., 1950.) 21*s*. net.

IN 1747 a lectureship in chemistry was instituted in the University of Glasgow and was first held by the famous teacher of medicine, William Cullen, followed by Joseph Black, John Robison, William Irvine, Thomas Charles Hope, Robert Cleghorn and Thomas Thomson. Soon after Thomson's appointment the lectureship was elevated to a regius chair, and this chair, it is stated, was "the earliest (1818) for chemistry, *tout simple*, in the country". The present incumbent, Prof. J. W. Cook, contributes a useful foreword to the book now under notice. In 1919 the Gardiner chair of chemistry was added, which Prof. J. M. Robertson now occupies. Dr. Kent points out that the Chemistry Department at Glasgow "in its first century was conducted single-handed and at times, indeed, only as an adjunct to other duties". A list is given of appointments to all grades of the academic staff of the Department up to the session 1947–48.

The scope of the book can be partly gauged by the subjects of the addresses and essays (and their authors) forming its chief contents: the lectureship at Glasgow (Dr. Kent); William Cullen's history of chemistry (Dr. Kent); Glasgow University in the eighteenth century (Prof. J. D. Mackie); Hermann Boerhaave and Scottish chemistry (Dr. Archibald Clow); William Cullen, M.D., and his times (Dr. Douglas Guthrie); phlogiston, caloric and heat (J. C. Gregory); Joseph Black, M.D.—the teacher and the man (Prof. John Read); Black's influence on chemistry (Dr. John A. Cranston); the industrial development of Scotland in the Cullen–Black period (Alexander Fleck); John Robison, M.A. (Sir Edmund Whittaker); James Watt and Glasgow University (Robert C. Howie); William Irvine, M.D. (Dr. Kent); early scientific links between Scotland and America (Dr. J. A. V. Butler); Thomas Charles Hope, M.D. (Prof. James Kendall); Robert Cleghorn, M.D. (Dr. George Thomson); Thomas Thomson, M.D. (Prof. J. R. Partington); some observations and an anecdote [Black and the teaching of chemistry, and Thomas Thomson] (the late Prof. T. S. Patterson); the chemical laboratory at Glasgow sixty years ago (the late Dr. Robert Broom); and Glasgow chemistry in the twentieth century (Prof. A. R. Todd). A prodigious amount of information is elegantly and most readably set forth. Numerous references to original sources, often extremely recondite, form a unique and invaluable collection.

It is almost inevitable that some controvertible statements have occurred in dealing with so much material. Thus, the unqualified assignment of 1774 as the year of Scheele's independent discovery of oxygen (p. 104) will surprise many. According to Nordenskiöld's researches, Scheele may have prepared oxygen as early as 1771; therefore then, or soon after, he may have observed its properties sufficiently to merit the use of the word discovery. In my opinion it seems impossible on available evidence to decide on any particular year whatsoever. On pp. 101–102 it is stated that Black discovered magnesium oxide, whereas even in his own famous paper some of the previous work of the great Friedrich Hoffmann is cited, including the ignition of what we now call magnesium nitrate, whereby the oxide is formed. Although magnesium compounds had been observed even before the investigations of Hoffmann, it is to him that the first clear and thoroughgoing publication of their characteristics belongs, based largely on his own admirable experiments. He clearly differentiated between magnesium and calcium oxides. But Black's epoch-making contributions to chemistry tower high above the discovery of magnesia. On pp. 157–8 a brief account of the early history of strontium contravenes the evidence assembled by Prof. Partington about this subject (*Ann. Sci.*, 5, 157; 1942. 7, 95; 1951). It was not Hope, but Crawford and Cruickshank, to whom is due the first known isolation of a strontium compound, the (hydrated) chloride. The treatment of the discovery of the oxide also requires considerable revision. In referring to achievements of Black's students, the statement (p. 46) that "Smithson Tennant developed the backward Cambridge school" is misleading, as his contact with Cambridge as a teacher was very brief. Appointed professor of chemistry in May 1813, he apparently delivered only one course of lectures, in April and May 1814. These lectures were probably excellent; but he died the next February on the Continent, where he had been for the preceding five months. As to the backwardness of Cambridge (presumably compared with Glasgow) at the time, this seems open to question, but I am unable to express an opinion based on enough study.

Partly in jest, one might say that the last three of the examples quoted give grounds for suspicion that respectable reverence for local gods has unwittingly influenced investigation and appraisement of their deeds. Be that as it may, every recorder of facts and their interpretations is liable to various psychological influences which he must guard against. This well-known fact should constantly be remembered, perhaps especially earnestly in these times.

It is hoped that the usefulness and charm of this book will be so widely recognized that future editions will be demanded. As well as corrections of textual errors, another desirable improvement would then be possible—in the indexes, where mentions of some persons in the text are not recorded, and those of others often only partially. There is something to be said for no index at all, rather than one having the air and intention of completeness which in fact it is far from achieving. A searcher relying on the latter kind may be denied information to be found, though with unnecessary difficulty, from reading the text.

Altogether, this is an indispensable text-book for students of the Cullen–Thomson period. Its price is moderate for the feast of knowledge and entertainment it affords.

L. F. Gilbert

UNITARY BIOLOGY

Cell and Psyche

The Biology of Purpose. By Edmund W. Sinnott. (John Calvin McNair Lectures.) Pp. ix+121. (Chapel Hill, N.C.: University of North Carolina Press; London: Oxford University Press, 1950.) 16s. net.

PROF. E. W. SINNOTT'S thoughtful and stimulating book is based on one forthright, far-reaching thesis. "The position which I wish to defend . . . is briefly this: that biological organization (concerned with organic development and physiological activity) and psychical activity (concerned with behaviour and thus leading to mind) are *fundamentally the same thing*" (p. 48). "It is this organization . . . which, *as experienced by the organism*, I believe to be the simplest manifestation of what in man has become conscious purpose" (p. 53). Sinnott is, of course, not the first to make suggestions of this kind. Somewhat similar attempts to avoid a bifurcation of Nature by refusing to admit the existence of a dualism are found in philosophies as different as those of Whitehead, the *Gestalt* school and Marxism. Sinnott's characteristic contribution is that he approaches the subject as a student of development. His professional biological interests bring him into immediate contact with those processes in which young organism is driven by its own internal constitution towards the realization of a specific end, th adult state—processes which strongly suggest parallel with those carried out by man under th guidance of a conscious purpose. Thus, whereas mos authors who have thought on these lines have been perhaps most interested in the problem of knowing Sinnott is particularly concerned with the problem of will.

It would certainly seem that, if we are ever t transcend the defeatist dualism of the conventiona outlook on biology, Sinnott has indicated the genera direction in which to seek a way of bringing the subjective experience of purpose into relation with materia events. There is no doubt that, particularly durin embryonic development, biological systems do sometimes get into states which result in a tendency fo change to occur in a definite direction. At present the examples of such states about which we know most do not involve the fully differentiated nervou system, but more simple systems in earlier stages o development. There is, however, no reason to den that similar situations of 'competence' might arise i the brain, and it would be to such conditions tha Sinnott would look to find the physical basis o will.

After developing these ideas in the first tw chapters, in the third Sinnott mentions briefly the relevance to some of the classical problems of philosophy. He attempts rather to show that his outloo may lead to a new formulation than to provid ready answers. Thus on p. 89 he writes, "The rea issue in the problem of freedom is again the fundamental character of biological organization, of wha it is that sets up self-regulating mechanisms in a livin thing, and ultimately in the nervous system of man and which thus creates purposes and fulfils them i action". This is hinting, surely, that there may b some close parallel between the 'spontaneous' formation of a purpose (that is, free will) and the sudde arising of a previously non-existent crystal orde when two suitable types of molecular species happe to come together in a liquid—a bizarre thought, bu perhaps not entirely unworthy of turning over in th mind. It is certainly a stimulating book.

C. H. Waddington

QUANTUM THEORY OF MOLECULES

Structure of Molecules and the Chemical Bond

By Y. K. Syrkin and M. E. Dyatkina. Translated an revised by M. A. Partridge and D. O. Jordan. P ix+509. (London: Butterworths Scientific Publications, Ltd., 1950.) 63s.

ALTHOUGH the quantum mechanical treatmen of atomic and molecular structure is now universally accepted, remarkably few monographs on th subject have yet appeared. This book, by Y. K Syrkin and M. E. Dyatkina, has already achieve recognition in its original Russian version, and th appearance of an English translation is therefore a event of some interest. During translation, certai additions and revisions have been made, and th intention evidently has been to provide a comprehensive and authoritative account of the subject f Western readers.

Certainly the field has been covered comprehen-vely, and the text is sprinkled with useful tables nd numerous references. These seem well chosen, lthough they show a certain bias to the Russian terature. Most of the treatment is qualitative, esting on the familiar resonance theory; but the athematical basis of the theory is also discussed in me detail. The style is adequate, and the book is ell produced and well indexed.

Unfortunately the authors have failed to make good se of their material and the book cannot be regarded s a success. In the first place, it seems to lack co-rdination, the chapters giving the impression of nplanned and disconnected essays. Thus most of he treatment of the Periodic Table in Chapter 2 ests on ideas of valency which are not discussed ntil Chapters 3 and 4, and spectroscopic notation s introduced in passing without any explanation. gain, there is a tendency to condense discussions of mdamental principles and enlarge on irrelevant etails; an example is the brief 'explanation' of esonance at the beginning of Chapter 5, followed by a igression on Rumer's theorem and a list of the rty-two canonical structures of naphthalene. Finally, he mathematical parts of the book seem particularly ept; some sections are obscured by vast smoke-creens of unnecessary algebra (the Heitler–London reatment of H_2^+ is a good example), while others uffer from ellipsis and lack of explanation (cf. the udden introduction of the secular equation on . 412).

There are various minor errors and omissions in the ext; for example, diethoxymethylene (p. 113) does ot exist, the bond-lengths quoted for dibenzyl (p. 76) re old and incorrect values, and the statement that oplanarity is essential for resonance (p. 95) is falla-ious. There are some misprints; for example, the mission of two exponents in Table 4, an incorrect esonance energy for chrysene in Table 113, and Mullian (corrected to Mullikan a few lines later) on . 133.

In short, this book cannot be recommended either s an authoritative text or as a suitable introduction o the subject. More experienced readers will find in it much useful factual information. The price seems high.

M. J. S. DEWAR

PHYSICS FOR GENERAL HONOURS STUDENTS

Physics

By S. G. Starling and Dr. A. J. Woodall. Pp. xvi+ 301. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1950.) 42s. net.

THE publication of a comprehensive text-book for students covering the whole subject of physics up to general honours degree standard is an mportant educational event, and in the short time ince it appeared there have already been signs of he cordial reception that this enterprise has deserved. Any volume of this standard planned to supplement ectures and give guidance to students would in these days of large classes and pressure on tutorial and ibrary resources serve a useful purpose and be sure f a welcome. It is all the more gratifying to find hat usefulness has not been submerged in the estricted principle of utility, and that the book can be recommended on its merits alone as an excellent companion for students, which is both sound in content and readable in presentation.

A good deal of elementary work is included, and it is a wise plan to take nothing for granted, for there can be few students who enter on work at this level with a full grasp of all that they are supposed to have mastered earlier; but this is presented in a way that will appeal to the maturing reader, and make him draw on his own resources instead of sending him back to refer to a first-year university text-book. Of the main contents, the electricity and magnetism portions follow the general lines of Mr. S. G. Starling's classic text-book for degree students, and the earlier chapters on the properties of matter again adopt the treatment that he has used successfully in the past, though to a slightly more advanced standard than in his earlier book. The sections on light, particularly the chapters dealing with physical optics, are well done, and the treatment of interference and diffraction is admirable; it is appropriate here to go fairly fully into details, since the elementary teaching at the school or intermediate level seems all so simple and almost complacently rounded off that the student's chief difficulty with more advanced work is to appreciate the physical necessity for a fuller mathematical treatment. The authors have here presented things so skilfully that the transition from what one might call the schoolboy outlook to the more exacting approach of university work comes naturally in the course of the text. The illustrations to this part of the book are helpful, and very well executed. The chapters on heat are perhaps a little below the standard of the rest; this is my opinion, which is based on a feeling that thermodynamics, as the most important of tools and the hardest with which to acquire proficiency, might well have been allotted more space. Other readers may possibly feel that a case could be made for a fuller treatment of this or that particular point; and criticism of this kind is no reflexion on the merit of the book, but rather emphasizes the high quality of what is actually provided, and the discretion and restraint with which the authors have aimed at, and preserved, a very uniform standard throughout the greater part of their work.

There are numerous references to modern developments in optics, electricity and atomic physics, and the principles involved are explained as fully as is desirable at this standard; but experimental details and matters of technique are wisely left for the student to seek elsewhere. This again is very laudable: people at this stage in their careers can stand on their own feet, and use initiative in pursuit of knowledge; but are often all too ready to use a text-book as a crutch if it is comfortably padded.

The first chapter gives a summary of the mathematical equipment required, and at the end of the book there are mathematical tables and a comprehensive list of physical constants. There is a collection of searching examination questions, and also, what is essential in a book of this size, an efficient index. Binding and production are good, and every device by which space may be saved without irritating the reader seems to have been adopted effectively, so that there is really more matter in the book than the respectable total of thirteen hundred pages suggests. At two guineas, in these days, it is very good value for money.

G. R. NOAKES

Inferiority Feelings in the Individual and the Group

By Oliver Brachfeld. Translated from the French by Marjorie Gabain. Pp. 301. (London: Routledge and Kegan Paul, Ltd., 1951.) 25s. net.

THIS book was written in Spanish by a Hungarian, translated into French and re-translated from the French into English. One might have expected from such metamorphoses that the result would be unintelligible; but so carefully has the translator, Marjorie Gabain, done her work that the text reads as if it had been written directly in English. The book is an attempt to show the historical emergence of Adler's ideas in such precursors as Montaigne, Hobbes, Mandeville, Vauvenargues, and so on, then the views of Adler himself, and finally their application to the individual and to society. The author draws on innumerable sources, both medical and literary, and is obviously widely read in most European languages. Most of the exposition of Adlerian principles merely follows the lines laid down by that school; but it is done in an interesting way. In some cases it is superficial and even contradictory; for example, the author is willing to accept the results of questionnaires regarding the superficial causes of inferiority, but he refuses to accept the fact that few musicians are deaf as a refutation of the Adlerian principle that musical ability is the result of over-compensation, as put forward by Elsa Bienenfeld.

The most interesting and original part of his book is the attempt to apply the theories of individual psychology to such problems as industrial disputes. It is long past time when psychologists should have made studies of the deeper causes of strikes and lock-outs, not from the point of view of benefiting either the employers or the employées, but to prevent them and the consequent disruption of society. A knowledge of the deeper causes of industrial warfare may help to prevent international disputes and the wreckage of society. Attempts, such as the author's, to understand the psychology of national feeling may finally give us a deeper knowledge and lead to prevention of war.

This book is a sound exposition of the Adlerian point of view and will interest those who find Adler's work satisfying. It is excellently produced, the paper is good, the print clear, and the binding in brown with gold lettering unobtrusive.

CLIFFORD ALLEN

The Electrical Activity of the Nervous System

A Textbook for Students. By Dr. Mary A. B. Brazier. Pp. x+220. (London: Sir Isaac Pitman and Sons, Ltd., 1951.) 25s.

THIS short text-book gives a useful elementary introduction to the electrophysiology of the central and peripheral nervous system and of the sense organs. Considerable knowledge of anatomy and physiology and some knowledge of elementary physics are required of the reader. The earlier chapters, which deal with the electrical properties and general physiology of peripheral nerve and of the spinal cord, are less detailed and self-contained than are the later ones, in which the peripheral and central sensory apparatus and the spontaneous electrical activity of the brain are described.

In these later chapters, the book ranges rather more widely and goes a little more deeply into its subject-matter than do the relevant sections of the standard texts on physiology. Medical students wil find in it interesting supplementary reading. Thos embarking on advanced courses in physiology wil not need it beyond the early stages of their work i electrophysiology, but they will find the bibliographies useful. The book will be specially valuabl to those physicists who are nowadays being attracte into the field of applied electrophysiology. Parts o it would interest general biological and scientifi readers.

The writing is admirably clear, the presentatio that of a gifted teacher and the many illustration have been wisely chosen.

The Physics of High Pressure

By Prof. P. W. Bridgman. (International Text-Book of Exact Science.) New impression, with Supplement. Pp. viii+445. (London: G. Bell and Sons Ltd., 1949.) 35s. net.

THE main achievements of the past twenty year in the high-pressure field are described in supplement of some forty pages, which is the chie addition to this new impression of Prof. P. W. Bridgman's standard work. Although this method of revision was probably dictated by the photographic process used, no happier way could have been chosen; for the story of the author's own monumental researches is continued beyond the range of pressures reached in the work of the original volume, up to 100,000 kgm./cm.^{2} in many cases, and this is the natural sequence to adopt. A number of new problems, such as the behaviour of metals under shear and plastic deformation at high pressure, are discussed as well as extensions of earlier investigations.

The only alteration in the body of the earlier text is in the section on the compressibility of the alkal metals. In 1931 it had seemed worth while to look for indications of the breakdown of atomic structure under the pressures then attainable. Redetermination of the values, and their extension to the highest pressure range, still fail to reveal any premonition of such breakdown, though in the case of cæsium two interesting discontinuities in the pressure–volume curve are recorded.

Apart from its uncontested authority as the work of reference on this subject, this is a book which the physicist with less-specialist intent can read with profit. It is a story of difficulties sought out and hunted down, written in a style which reveals the author as one of the calmest and most equable of experimenters. His comments and discussion are rich in scientific wisdom, and it is good to see the book once again in print.

Scientific Survey of South-Eastern Scotland

Prepared for the Meeting held in Edinburgh, 8th to 15th August 1951. Pp. 208. (Edinburgh: British Association Local Executive Committee, The University, 1951.) 15s.

THIS book was prepared in connexion with the meeting at Edinburgh this year of the British Association for the Advancement of Science, and, on the lines of surveys for other years of the locality around previous meeting-places of the Association, it gives a comprehensive but succinct account of the history, social conditions and economy of south-east Scotland as well as its scientific features, natural and otherwise. The area covered is made up of the counties of Fife, Kinross, West Lothian, Midlothian, East Lothian, Peebles, Berwick, Selkirk and Roxburgh

—that is, roughly speaking, all the land from the Cheviot Hills to the Firth of Tay lying on either side of the Firth of Forth. The book is divided into twenty-one review articles, each by a local authority and dealng respectively with the following topics: south-eastern Scotland—the region and its parts; weather and climate; prehistoric settlement; the Roman period; medieval times; 1500–1950; growth of Edinburgh, 1128–1800; growth of Edinburgh, 1800–1950; public health; influence of man on plant and animal ife; agriculture; mining; manufacturing industries; changes in rural life and landscape, 1500–1950; population; transport; education; University and colleges of Edinburgh; the outlook; geology; esearch institutions. To complete the work a Bartholomew quarter-inch coloured topographical map is included, tucked into a flap on the inside of the back cover.

In the space of a short note it would be invidious to select any particular item for detailed comment, but perhaps it might not be inappropriate to say that, since paper-making and printing and book-binding are mentioned as among the principal industries of Edinburgh, one could expect that the production of this book would be of a high standard —and one's expectations are fulfilled. As befits the capital city of the northern half of the Union (and there are some, Sassenachs included, who would describe it as the fairest city of the Union) a good proportion of the space is devoted to Edinburgh itself; but a capital city is not the be-all and end-all of a country, and it can be fairly said that south-east Scotland as a whole has received its due share.

While the appeal of this type of survey is necessarily limited to those with ties to the immediate locality in question, nevertheless the members of the British Association who conserve these annual volumes thereby collect an authoritative collection of material pertaining to the principal centres of Great Britain, and this volume is second to none in this series.

Introduction to the Patenting of Inventions

By Cecil Hollins. Pp. 99. (London: Ernest Benn, Ltd., 1951.) 4*s*. 6*d*. net.

MR. CECIL HOLLINS and his publishers are to be congratulated on producing in ninety-nine pages and for 4*s*. 6*d*. such a concise and straightforward account of the essentials of that complicated and important field of law—British patent law. Mr. Hollins is exceptionally well equipped for producing such a book. For many years he was head of the Patent Department of the Imperial Chemical Industries, Ltd., and he has also had a wide experience on patent and related matters in Great Britain and abroad. He is therefore fully aware of the needs of scientific and technical persons in relation to the important questions of patents, and this book should make a great appeal to inventors and persons engaged in research generally and to members of the staffs of industrial firms.

In January 1950 the Consolidated Patent Act, 1949, came into force and made many important changes in patent law. Most of these amendments had been recommended by the departmental committee on patents presided over by Sir Kenneth Swan. Mr. Collins's book deals briefly with all the provisions of this Act. Chapters 1 and 2 deal with questions likely to arise in the course of prosecuting patent applications, and Chapter 3 is concerned with questions after a patent is granted. In Chapter 4 he indicates briefly the grounds upon which a patent may be attacked for invalidity.

The book is well set out, with the main headings printed in heavy type, and marginal references to the sections of the Act are included in the text. For a small book of this kind, the index is exceptionally good, and an attractive feature is that this index refers both to the pages of the book and to the sections of the Act. It is therefore a complete index to the Act, irrespective of the contents of the book. There are references to some important court cases, but the book has the advantage of not being cluttered up with references to many cases which the new Patent Act has put out of date. R. G. LLOYD

Australian Fisheries

A Handbook prepared for the Second Meeting of the Indo-Pacific Council, Sydney, April 1950. Edited by I. G. MacInnes. Pp. 103+6 plates. (Sydney: Commonwealth Fisheries Office, 1950.) n.p.

THIS handbook gives a balanced and informative picture of a young and vigorous fishing industry expanding in spite of the handicap of a general low level of productivity in the surrounding seas. The freshwater fisheries of Australia are of little importance; but the estuarine fisheries are very important, so much so that it is a pity that statistics for these fisheries are not given. The deep-sea trawling and seining fisheries contribute 16 million out of an estimated total production of some 91 million pounds of fish in 1948–49; it is the distribution of the balance which would be so informative, and one has to search through the text for such statistical data as are given.

The lack of statistical tables, however, is the only criticism in a most useful booklet. The fine work being done by the research staff is summarized; in more than one instance this research has led directly to new fishing industries.

The distribution of the existing fisheries is shown, and explained in terms of produce and markets. The expansion of canning and freezing may, however, open up fisheries in sparsely populated areas, as has already happened in the case of Tasmania. Six useful plates illustrate the principal Australian fishes of commercial importance. C. F. H.

Journal of the Institute of Metals

Editor: Lieut.-Colonel S. C. Guillan; Assistant Editor, Major W. G. Askew. Vol. 75, 1948–49. Pp. lii+1230+138 plates. (London: Institute of Metals, 1949.) 60*s*.

THE Institute of Metals attempts the difficult task of providing a society to serve the interests of those concerned with the industrial side of non-ferrous metallurgy, and of purely scientific workers. The present volume shows how admirably this dual function is fulfilled on the publication side. It contains fifty-four papers covering such a wide range that any metallurgical reader will find much of interest. The standard of printing and illustration is high, but the volume of 1,230 pages is far too bulky and should have been split into two parts or separate volumes; the bound copy sent for review will rapidly become detached from its cover in the course of normal laboratory use. The papers include six contributions to a symposium on metallurgical aspects of non-ferrous metal melting and casting of ingots for working, and apart from this the wide range of subjects is remarkable. W. HUME-ROTHERY

INSECT PHYSIOLOGY AND APPLIED ENTOMOLOGY

A MEETING of the Association of Applied Biologists, held in the rooms of the Royal Entomological Society of London on October 12, was devoted to "Insect Physiology in Relation to Applied Biology". Dr. V. B. Wigglesworth was in the chair.

In opening the discussion, Dr. Wigglesworth claimed that insect physiology makes no direct contribution to applied entomology. The control of insect pests by biological methods is based upon ecology; but a proper understanding of the ecology of an insect is impossible without a knowledge of its physiology. The practical value of this knowledge lies in the new ideas that it gives to the applied entomologist. Similarly, all the greatest discoveries in the use of insecticides have been made empirically. But the subsequent study of the diverse physiological mechanisms involved in insecticidal action has served to codify our knowledge, to put it on a rational basis and to point the way to further advances.

The study of insecticidal action may be pursued at three levels: the uptake of insecticides from the environment, their passage through the protective coverings of the insect or its egg, and the intervention of insecticidal poisons in metabolism. Dr. W. A. L. David discussed the physiological and anatomical factors involved in the accumulation of contact insecticides. The movement of the insect plays a most important part; and, as Dr. E. A. Parkin pointed out later in the discussion, the insecticide may itself influence the insect's movement and so the quantity of poison it acquires. Insects walking on a treated surface will pick up increased amounts of poison. The fine droplets that compose insecticidal mists will strike the insect only if they have sufficient momentum or if the insect itself is moving rapidly enough. They are, indeed, effective as a rule only if the insect is in flight, and, since the wings of flies or mosquitoes commonly move at least ten times as fast as the body, by far the greater number of droplets are taken up by the beating wings. Many different factors have to be considered in the accumulation of insecticidal dusts by insects. Some dusts are physically bulky, others dense; and the appearance of the treated insect may give a totally misleading impression of the weight of dust accumulated. In the case of rough or hairy insects, large amounts of the dust collected may be quite out of contact with the effective sites of entry; and with a single species of insect the same amount of the active principle accumulating on the body may be more effective when associated with one carrier than with another, because the shape of the dust particle has an important influence in ensuring contact with the vulnerable areas.

Dr. J. W. L. Beament pointed out that recently acquired knowledge of the structure of the cuticle and egg-shell of insects goes some way to explain the variable toxicity of contact poisons. In both the cuticle and the egg-shell a thin layer of wax forms the most important barrier; an insecticide must dissolve in wax and have a suitable partition coefficient between oil and water. Local differences in the structure of the membranes demand detailed study. In the egg of Heteroptera, for example, the general surface is totally impermeable to the most potent poisons. But around the rim of the cap are respiratory ducts containing an air-filled, spongy substance leading to a thin layer of the same air-filled material lining the shell. Insecticides with suitable wetting properties will readily fill layers of this type, which are of common occurrence in insect eggs, and they are then separated from the contents of the egg only by the thin wax layer. Some eggs deposit a further layer of impermeable material inside the wax. The formation of this layer may be correlated with a great increase in the resistance of the egg to insecticides when it reaches a certain age. It may become susceptible again in the late stages of development when this inner membrane is dissolved; or the embryo may be poisoned by the quantities of insecticide that have been held in this protective membrane and liberated during its solution. Clearly the age of eggs must be most carefully controlled in making ovicidal tests.

Dr. C. Potter described a number of researches by himself and his colleagues, Dr. K. A. Lord and Dr. A. H. McIntosh, which served to illustrate some of the physical and biochemical factors concerned in insecticidal action. The size of particles of an insecticide applied externally may greatly influence the toxic action. Small particles of rotenone are several hundred times more toxic than layer particles. With DDT the difference is less evident—perhaps because it is so much more soluble in the lipoid layer of the cuticle that its rate of entry is not greatly influenced by being in finely particulate form. The same correlation between the effect of particle size on toxicity, on one hand, and lipoid solubility, on the other, is seen when the poisons are injected into the blood stream. Temperature may influence the toxic action of insecticides in several quite different ways. Pyrethrins, DDT and some other poisons are much more toxic if the insects are kept at a low temperature after spraying. This is mainly an effect on metabolism. But at high temperatures insects move more actively; they may therefore pick up more of the insecticide from the environment and thus show an increased mortality at higher temperatures. Moreover, at low temperatures the more rapid solubility of small particles is accentuated so that their relative toxicity is even greater. The action of insecticides in metabolism was illustrated with reference to the organo-phosphorus compounds. These are powerful inhibitors of choline-esterase, and when an analogous series of organo-phosphorus insecticides is examined there is a partial correlation between choline-esterase inhibition and toxicity. But there are other esterases present in insects which do not hydrolyse acetylcholine, and it has been found that these also are inhibited by the organo-phosphorus insecticides; and it may well be that this effect is involved in their insecticidal action—for example, when they kill insect eggs at an early stage of development. A knowledge of the differences between the esterase systems of insects and mammals might serve as a basis for selecting chemicals toxic to insects but relatively non-toxic to man.

The interrelations between physiology, ecology and cultural control were illustrated and discussed with reference to the sheep tick *Ixodes ricinus*, an important carrier of a number of serious diseases in sheep on hill farms. Dr. A. Milne described the general features in the ecology of this tick. It is widely spread throughout the hill sheep-farming areas of Great Britain, but occurs only in those localities where the pastures are rough, with a thick layer or 'mat' of dead and dying vegetation at the base of the herbage. The humidity in this mat is always about 100 per cent, and it appears to be this high humidity which is the limiting factor in the distribution of the tick. This is not surprising when it is realized that the sheep tick is not resistant to desiccation, and yet during its life-cycle of two to three years it spends only about six weeks in feeding on its host. For the rest of its life it is lying inactive in the moist mat or is at the tips of the grass stems waiting for a passing host. In most of the country there is only one period, in the late spring and early summer, during which the ticks are active in this way. But there are some localities, notably in the west of England, where there is a second peak of activity in the autumn. (An apparent peak in the summer which has been described in Wales is spurious and has been wrongly inferred from the gradual rise in the numbers of ticks upon stock introduced to infested pastures.) Pasture improvement, with the elimination of the humid 'mat', will effectively eradicate the sheep tick—though this is seldom economically practicable on the hill farms.

Dr. J. Allan Campbell described his detailed studies of the developmental cycle of the sheep tick in Nature. The temperature in the natural environment ranges between -2° C. and $+15^\circ$ C. At these temperatures development and egg-laying proceed at much slower rates than has been inferred from studies in the laboratory. In the normal cycle the tick at each stage of its development feeds in the spring or early summer, moults or oviposits during the summer, and overwinters in the unfed state. But there is a second cycle in which the ticks feed in the autumn, pass the winter in the egg or in the engorged state, and hatch or moult in the spring. It is these two populations, between which there seems to be little interchange, which are responsible for the two peaks of activity in the spring and in the autumn. The threshold temperature for development of the egg is 7° C.; but the eggs laid by the ticks of the autumn feeding cycle will not develop, even at 10–20° C., until they have been exposed to severe cold for a good many weeks.

The physiology of the sheep tick, as described by Dr. A. D. Lees, goes far towards explaining the observations made on its ecology. When compared with a series of other ticks, *Ixodes ricinus* has a cuticular wax of very poor waterproofing powers, and it is this which limits its distribution. The closely related dog tick *Ixodes canisuga*, which has a cuticular wax of higher melting point, is alone able to survive in the kennels of the sheep dogs, although both species are picked up by them. So long as *Ixodes* remains in a nearly saturated atmosphere, it can absorb water vapour actively through its cuticle and maintain its water content. When it becomes active in the spring, the unfed tick shows a negative response to gravity and an avoidance of high humidity which lead it to the tips of the grasses, where its sensitive responses to vibration, to passing shadows and to eddies of warm air and smell enable it to cling to a passing host. The unfed tick at each stage of its life-cycle can remain latent in the humid mat for many months. The length of time it can resist starvation is determined by its reserves of fat carried over from the previous stage. After becoming active and resting for some time at the tips of the grasses, it loses moisture and it then returns to the mat to restore its water content by the active uptake of water vapour. This form of activity is necessary if the tick is to secure a meal to enable it to grow or reproduce. But it soon exhausts the limited reserves of fat, and the active tick dies of starvation far sooner than the more sluggish individual which remains dormant at the base of the vegetation.

In closing the discussion, Dr. Wigglesworth said that the sheep tick problem was chosen because it illustrates particularly well the way in which a knowledge of the detailed physiology of a pest enables the applied biologist to think clearly and rationally about it and to see his problems in a new light. That is part of the debt of applied entomology to insect physiology. But there is a debt of perhaps even greater magnitude in the other direction. Many of the most important discoveries in insect physiology, and indeed in biology in general, have resulted from the intellectual stimulus of contact with some practical problem.

BUILDING RESEARCH CONGRESS, 1951

THE Building Research Congress held in London during September 11–20 was the outcome of co-operation between some two-dozen professional institutions and trade federations interested in building and civil engineering construction, the Department of Scientific and Industrial Research and the Ministry of Works. As the first of its kind ever to be held, it aroused much interest both in Great Britain and overseas, and among its 1,400 members were representatives of more than fifty countries; of the eighty-eight papers presented forty-five were by authors from outside Great Britain. The enthusiasm with which the Congress was greeted was a clear indication of the need for such a conference, and the large attendance from abroad was a tribute to the regard in which the pioneer work of Great Britain in this field is held. The Congress, the organization of which was largely undertaken by the Building Research Station of the Department of Scientific and Industrial Research, met under the presidency of Lord Samuel.

The opening session, held at the Institution of Civil Engineers on the morning of September 11, was the occasion of the first of Lord Samuel's thought-provoking contributions. He directed attention to the effect environment—man-made as well as natural—has had on individuals and pointed out the effect that building research could therefore have on individual and national life. Dr. F. M. Lea, director of building research in the Department of Scientific and Industrial Research, traced the growth of organized building research and made a plea for still closer co-operation of industry in the application of its results. In the afternoon members were the guests of the Government at a reception at Lancaster House, and later, under the auspices of the Parliamentary and Scientific Committee, visited the new House of Commons Chamber and other parts of the Palace of Westminster.

For the technical sessions, the Congress was organized in three divisions, dealing with the engineering and constructional problems, with building materials, and with the factors affecting the use of buildings. For most of the period of the Congress there were thus five concurrent sessions; the papers, all of which had been specifically invited, had been circulated before the Congress and were therefore only briefly introduced, so that most of the time was available for discussions, which were at all times lively.

The first two sessions in Division 1 were devoted to papers dealing with the influence of mechanization and prefabrication on techniques and cost of building. After a general review had been given by R. Fitzmaurice (Great Britain), there were papers from Holland, the United States and France, on the latest developments in the building of dwellings in these countries. It was apparent that there is still a good deal of work in progress on non-traditional construction. Research into the use of mechanical aids in building operations was covered in a paper dealing with work in Great Britain, and it was pointed out that the full application of aids of this sort has yet to be effected. The last paper in this group was from Switzerland and dealt with the changes which new building methods bring into design and drawing-office procedure. Perhaps the main feature brought out in the discussion of this group of papers was the slow effect innovations have on the structure and techniques of so traditional an industry.

Three sessions were then devoted to the influence of modern research on structural design, in which a general review paper was given by Prof. G. Wastlund (Sweden). A group of four papers dealt with research on the use of concrete in structures, and considerable interest was aroused particularly in the two papers in this group which dealt with pre-stressed concrete and the design and use of thin concrete shells. A further four papers dealt with research into the use of steel in structures; and these papers covered such points as the way in which research has been helping the designer, research on structural steelwork particularly with reference to the behaviour of structures beyond the elastic range, and the application of welding in steel structures. A third session in this group was devoted to timber and light alloys; in this session there was a paper dealing with the modern development of the use of glued laminated timber as a structural material.

The final two sessions in Division 1 were concerned with the influence of modern soil studies on the design and construction of foundations, and it was fitting that the introductory paper should have been written by Prof. K. Terzaghi (United States). The other papers presented were drawn from the United States, Great Britain, Canada and Holland.

The proceedings of Division 2 opened with an introductory paper by Dr. T. W. Parker, deputy director of building research, Department of Scientific and Industrial Research, on general trends in research on building materials, in which reference was made to the importance of pursuing an adequate measure of fundamental research, despite the pressing demands of day-to-day technical problems, and to the need for the co-ordination of information on materials so that each may be used to the best advantage to meet the overall functional requirements of the building. The remainder of the proceedings were concerned with papers from Britain, Canada, Australia, South Africa, the United States, France, Holland and Germany, on varied aspects of research on the production, properties or utilization of the main building materials.

Four papers on the weathering and durability of building materials generally and another on the durability of concrete in engineering structures demonstrated the complexity of a subject that covered the whole range of building materials under temperate, tropical and sub-arctic conditions, and revealed much common ground of observation and experience.

Papers on burnt-clay products described developments in manufacturing processes induced in some measure by the need for economy in the use of both fuel and labour, and showed evidence of the growing recognition by the industry of the part that new fundamental knowledge of the nature of clay can play in guiding technical control of the operations. A survey was presented of the work that has been done, mainly in Great Britain, on the structural performance of burnt-clay products in respect of strength, resistance to rain penetration, fire resistance, and other functional requirements—investigations that provide a sound basis for framing codes of practice and building by-laws.

Contributions from the United States, Britain and France on the quality control of concrete on building sites showed that substantial advantages can be gained by the adoption of an organized system of control. Concrete of the quality specified in a contract can be secured with a reduced consumption of cement. Appropriate change in the conventional form of specification would provide an incentive to take economic advantage of the use of quality-control methods.

The economic and functional merits of light-weight concretes were discussed, and a review was presented on the effects of curing concrete at elevated temperature, each with comments on the directions in which there is still scope for fundamental and technical investigation.

Two papers dealt with the utilization of building stone with particular reference to means for reducing costs. One referred to the adoption of a restricted range of standard sizes of block stone in the French Standard *B*10-001 and described the construction and performance of the machines that have been developed in France for winning the stone from the quarry face and for its subsequent preparation. The other paper, based on a recent survey, set out the present differences in the cost of building houses in stone and in brick in the more important stone-producing districts of England and Scotland, and suggested ways in which the cost of building houses in stone might be reduced.

A contribution on the burning and hydration of lime described physicochemical studies that have been undertaken in South Africa with the object of explaining and eliminating building defects attributed to unsoundness in certain magnesium limes used there. Other papers dealt with the production, properties and uses of calcium sulphate plasters, with paint application, and with developments in limewash and cement paints.

The proceedings of Division 2 concluded with the presentation of three papers on timber technology. One, on the resistance to wear of timber flooring, described the development of testing equipment to reproduce qualitatively and quantitatively the wear effects observed in service; another described investigations on the use of plywood as a building material; and the third, investigations on the durability and preservation of timber.

Division 3 concerned light, heat and sound in buildings, and design research on three types of buildings—hospitals, factories and schools. Papers had been invited from authors in Great Britain, United States, Sweden, Holland, Germany, Austria, South Africa, Australia, Switzerland and France.

In the group of papers on lighting research and its application to building problems, the four main aspects of the problem were each treated in turn. First there was a group of papers dealing with the brightness pattern of the work (meaning the particular object of attention) and its surroundings. Then came a group of papers dealing with sources of artificial light, where the difficulty is to get desired levels of lighting on the work and elsewhere without these sources sending too much light directly into the observer's eyes. The same sort of problem was stressed in the group of papers on the use of daylight, where the window is the source of light. The final group of papers was on the use of colour, by which one factor in brightness is controlled. Papers in this group on lighting made their contributions through the study of principles, of measurement and of subjective investigation, all being applied to the buildings themselves.

In heating, the range of the subject-matter discussed was wide both in methods and geography. There were papers on laboratory and analogue studies, on full-scale experiments, and on the problems presented by the range of climates from temperate to tropical. The effect of building design, and especially of thermal capacity, was found as an influence in most of the papers and discussions, especially in relation to the problems of non-steady heating. These same factors appeared also in the consideration of tropical buildings where thermal capacity is one of the main design factors by which tolerable conditions can be obtained when expensive cooling equipment cannot be used. In the session devoted to the design of heating plant, an interesting recent technique reported was the use of high-pressure hot-water systems using temperatures as high as 350° F. (176·7° C.) with consequent savings in size and cost of heating services.

The group of papers on sound were centred round the topical acoustical problems associated with auditoria and broadcasting studios. Once again, the range of matter discussed was wide, and extended from the contribution which recent theoretical developments in acoustics may be able to make to design as compared with older geometrical and statistical methods, to the consideration of the very large halls which are a feature of United States auditoria and which seat upwards of five thousand people. The particular problems of broadcasting studios were discussed in papers from Great Britain and Switzerland, as were open-air auditoria, general-purpose halls and halls designed specifically for musical purposes.

Towards the end of the Congress three sessions in Division 3 were devoted to the study of three particular types of building. One session was devoted each to hospitals, factories and schools. This application of building research is a recent development, and it is perhaps surprising to find the strict way in which experimental techniques can be, and are being, used in architectural design research. This was most strikingly demonstrated in the hospital section, where detailed observations of the use and administration of wards have led to a new thesis in planning which is now to be the subject of full-scale experiment. The schools section revealed an equally interesting innovation in the use of large-scale industrial development methods for the production of high-quality schools of various types. The section on factories was notable for the stress laid on the contribution the architect can make not only to the appearance of the building itself, but also to the detailed planning and arrangement of its interior in terms of the work to be done inside the building.

It is appropriate that the closing meetings, on September 20, should have taken place in the Royal Festival Hall, which is itself an outstanding contemporary example of the application of building research. No formal summing-up of the Congress was attempted; but at the morning session a number of members from overseas gave their impressions of the effect the Congress might have on the problems of their countries. Several of those who spoke took the opportunity of suggesting that smaller and more specialized conferences might be arranged in the future and then followed by another comprehensive congress after a period of several years. In the afternoon, Sir Ben Lockspeiser, secretary of the Department of Scientific and Industrial Research, gave an address in which he directed attention to the urgent need for the fuller application of the results of the work of men of science in this field.

LOCALIZATION OF GUSTATORY AND OLFACTORY ENZYMES IN THE RABBIT, AND THE PROBLEMS OF TASTE AND SMELL

By A. F. BARADI and Dr. G. H. BOURNE

Department of Histology, London Hospital Medical College, E.1

IT has been shown[1] that alkaline glycerophosphatase is localized in the gustatory regions of the tongue in a number of mammals (bat, rabbit and man) and in the olfactory mucosa of the rabbit. Since then, Baradi and Bourne[2] have shown that a simple esterase is present in the taste buds and epithelium of the papilla foliata of the rabbit, and that the histochemical reaction for this enzyme was inhibited by the addition of quinine to the substrate mixture and the glycerophosphatase reaction by vanillin.

In addition to these two enzymes, we have found that enzymes are present in the papilla foliata and the olfactory mucosa of the rabbit which split various substrates, such as hexose diphosphate, adenosine triphosphate, muscle adenylic acid (5-nucleotidase, Reis[3]), yeast adenylic acid (3-nucleotidase), nucleic acid (probably ribonuclease), long-chain fatty acids (lipase), alpha-glycerophosphate at pH 3–5 (acid phosphatase). The distribution of these enzymes in the papilla foliata is shown in Fig. 1. In general, one can say that all the enzymes are located in the epithelium lining the folds between the papillæ, although some are present in addition in the neighbouring epithelium. Acid phosphatase is present in only small amounts at the bases of the papillæ; ribonuclease is present only in the epithelium immediately overlying the taste buds; esterase and acid phosphatase are present in taste buds and in Ebner's glands; and the enzymes which split yeast and muscle adenylic acid appear to be present in all nuclei in the preparations, as well as in the cytoplasm of superficial epithelial cells.

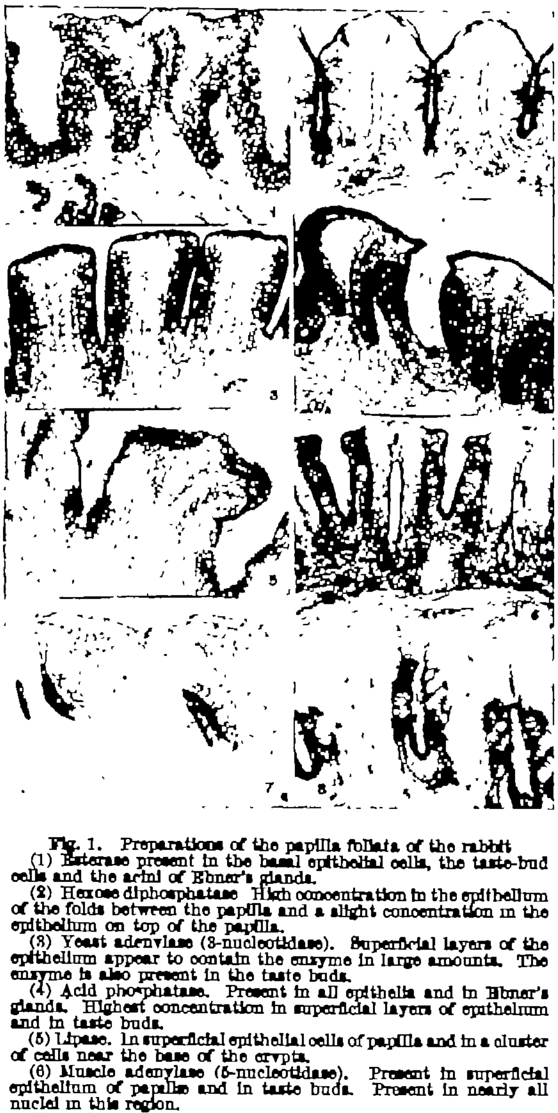

Fig. 1. Preparations of the papilla foliata of the rabbit

(1) Esterase present in the basal epithelial cells, the taste-bud cells and the acini of Ebner's glands.

(2) Hexose diphosphatase High concentration in the epithelium of the folds between the papilla and a slight concentration in the epithelium on top of the papilla.

(3) Yeast adenylase (3-nucleotidase). Superficial layers of the epithelium appear to contain the enzyme in large amounts. The enzyme is also present in the taste buds.

(4) Acid phosphatase. Present in all epithelia and in Ebner's glands. Highest concentration in superficial layers of epithelium and in taste buds.

(5) Lipase. In superficial epithelial cells of papilla and in a cluster of cells near the base of the crypts.

(6) Muscle adenylase (5-nucleotidase). Present in superficial epithelium of papillæ and in taste buds. Present in nearly all nuclei in this region.

(7) Nuclease (probably ribonuclease). Present only in epithelium immediately on top of taste buds.

(8) Effect of adding quinine to ribonuclease substrate mixture in which slide was incubated. All epithelium between papillæ shows high concentration. Enzyme also now present in taste-bud cells.

The distribution of enzymes in the nasal mucosa is shown in Fig. 2. All the phosphate-splitting enzymes are concentrated entirely in three or four basal cells in the olfactory epithelium. As centres of enzyme activity these cells appear comparable with the stratified epithelial cells which line the folds in the papilla foliata. The ducts of Bowman's glands are positive for alkaline glycerophosphatase but the glands are negative. However, they are positive for lipase and esterase. Lipase is only present in this site; but esterase is present in all the cells of the olfactory epithelium as well.

The localization of these enzymes in and around the gustatory and olfactory organs in the rabbit suggests that they may be associated in some way with the mechanism of smell and taste.

It has been suggested by Kistiakovsky[4] that the mechanism of smell could be explained by the existence in the olfactory mucosa of four enzyme groups (one for each of the theoretical basic smells), and that odoriferous substances are distinguished by their differential inhibition of particular enzyme groups. The same explanation might be used to account for a mechanism capable of distinguishing between substances of different taste.

At the time Kistiakovsky's suggestion appeared, we had already tried out the *in vitro* effect on the gustatory enzymes of a number of substances with a well-defined taste. These had been added to the substrate solutions used for localizing the enzymes. Complete details will be published elsewhere, but we refer here to a few of the more outstanding results. Vanillin (0·05 per cent) inhibited glycerophosphatase activity but had no effect on any other reactions. Tea infusion inhibited esterase and ribonuclease reactions. Sucrose had no effect and saccharine inhibited esterase. Quinine inhibited the glycerophosphatase, the 5-nucleotidase and the esterase reactions and greatly *increased* the ribonuclease reaction. Some inhibition of the ribonuclease, 5-nucleotidase and 3-nucleotidase (yeast adenylic acid) reaction was obtained by adding enough sodium chloride to the substrate mixture to bring its concentration to twice that of normal saline. Capsicum, aniseed, peppermint and coffee also caused differential inhibition of the various enzyme reactions.

The accentuation of the ribonuclease reaction by quinine suggests that the enzyme was in these sites

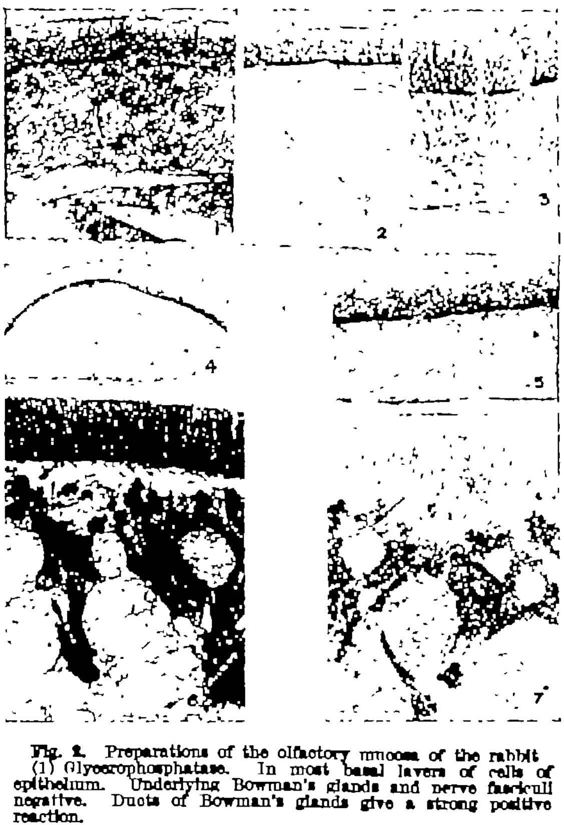

Fig. 2. Preparations of the olfactory mucosa of the rabbit

(1) Glycerophosphatase. In most basal layers of cells of epithelium. Underlying Bowman's glands and nerve fasciculi negative. Ducts of Bowman's glands give a strong positive reaction.

(2) Hexose diphosphatase. In most basal cells of epithelium only.

(3) Adenosine triphosphatase. Present only in most basal cells of epithelium.

(4) 5-Nucleotidase. Principally in most basal layer of epithelial cells. All nuclei are positive. The enzyme also present on surface of epithelium.

(5) 3-Nucleotidase. Principally in basal layer of cells of epithelium. More superficial cells of basal cells also positive.

(6) Esterase. All basal cells of epithelium intensely positive. Olfactory cells also positive. Bowman's glands intensely positive. Nerve fasciculi negative.

(7) Lipase. Only Bowman's glands positive.

before, but at too low a concentration to give a positive result. The amount of quinine used (0·5 per cent) would have been sufficient to combine with all the substrate present and may have facilitated its splitting by low concentrations of the enzyme. It seems probable that all these substances may exert their effect by combining with the substrate. The possibility of some interference with a co-enzyme must, however, also be considered. It is also of interest that the *dl*-isomer of tryptophane, which is sweet, inhibits the glycerophosphatase reaction, and the *l*-isomer, which is bitter, has only a slight inhibitory effect.

A number of technical criticisms may be made of this work, and if they were correct they may to some extent invalidate it. These are: (1) Is there a non-specific attraction by the apparent sites of enzyme activity for some of the reaction products (for example, calcium phosphate)? (2) The enzyme may be present in a particular site and give no reaction[3]; this is supported by the way quinine causes a positive ribonuclease reaction in otherwise negative sites. (3) Are we demonstrating one phosphate-splitting enzyme or a number of such enzymes? (4) Are the inhibitions of activity true interference with enzyme substrate reaction, or do they simply represent interference with the histochemical reaction, for example, prevention of deposition of reaction product?

If (1) were correct, all phosphate-splitting enzymes would have an identical distribution. They do not. Also, at the suggestion of Prof. J. Danielli, calcium phosphate was precipitated by adding hydrogen peroxide to the incubating medium over a section in which enzyme activity had been destroyed. There was no particular affinity on the part of the sites of enzyme activity for the calcium phosphate. The second criticism may be correct, but we claim only that positive results indicate the presence of enzyme and we do not deny that it may be present in apparently negative sites. In fact, our results indicate that it may be present in such sites. In the case of (3), it may be that glycerophosphatase, a known non-specific enzyme, may contribute to some extent to the results obtained with other substrates; but different distribution, together with differential inhibition (apart from other independent evidence), strongly suggest that we are dealing with a series of different, though probably closely related, enzymes. If the inhibitions represent only interference with the histochemical test (4), then, for example, any substance which inhibits one phosphate splitting enzyme will inhibit them all. This is not the case, and, in fact, one inhibitory substance (quinine) actually accelerates the action of another phosphate-splitting enzyme. Further discussion of this problem will be given in subsequent publications, but at the moment we believe that these inhibitions represent true interference with enzyme substrate reaction, even allowing for the well-known variability of histochemical preparations.

If we assume, therefore, in the absence so far of any contradictory evidence, that these enzymes are localized in the sites described, and that their action is inhibited or accelerated by various substances with pronounced taste, we are impelled to ask in what way such a mechanism could explain any of the phenomena of taste.

Generally speaking, the enzymes we have studied are localized in six main sites. Furthermore, there is an abundant nerve supply[6,7] to the epithelium of the papillæ as well as to the taste buds.

Taking these facts into consideration, we suggest the following tentative hypothesis to explain their relation to the mechanism of taste. The chemical reaction involved in the breakdown of substrate by enzyme presumably gives rise to ionic changes which would induce currents in nearby nerve fibres. We can then conceive of a tasting substance coming into contact with superficial enzyme sites. It would inhibit the activity of an enzyme in one site, accelerate the activity of an enzyme in another site and have no effect on enzymes in other sites and so on. It would therefore alter the pattern of nerve impulses reaching the brain, and each substance would produce its own individual pattern. Since there are six main sites of enzyme activity, each of which can be accelerated, inhibited or left unaffected, we have a mechanism for distinguishing between 2,160 tasting substances. This hypothesis therefore makes the conception of four basic tastes unnecessary. It also suggests that the taste buds are not the sole organs of taste, but that they are only reference or focusing points to which the brain can relate impulses coming from other sites; in other words, they give precision to taste.

This hypothesis also serves to explain why substances of widely differing chemical nature can have a similar taste. The distribution of the enzymes overlaps at the various sites; therefore inhibition of *different* enzymes at the *same* sites by *different* substances will produce the same pattern of nerve impulses, which will be interpreted by the brain as the same taste.

The same hypothesis can probably be used to explain the sense of smell. Most of the gustatory enzymes have also been found in the olfactory mucosa (and are inhibited in the same way). Here again we feel that the sense of smell may not be the sole property of the so-called olfactory cells but that these cells may act only as reference points with relation to the rest of the olfactory mucosa and that, in fact, they may function in the same way as the taste buds in the tongue.

There are almost certainly very many more enzymes in the gustatory and olfactory regions, but we are limited in this work to those which can be localized histochemically. There are still some, for which histochemical tests exist, which we have not yet tried. Nor have we yet taken into account the significance of the distribution of certain enzymes in Ebner's and Bowman's glands.

This conception of taste and smell can, of course, be only of a provisional nature and it may, in the light of future work, be subject to substantial alteration. Nevertheless, we find it useful at the present moment as a working hypothesis.

The phosphate-splitting enzymes were demonstrated by the technique described by Gomori[8], the lipase also by a Gomori method[9] and the simple esterase by Gomori's unpublished modification of the Nachlas–Seligman method[10].

We are indebted to W. J. Bush and Co., Ltd., for a supply of essential oils and essences used in this work.

ANNIVERSARY OF TRANS-ATLANTIC RADIO

By Dr. R. L. SMITH-ROSE

On December 12, Marconi's Wireless Telegraph Co., Ltd., is celebrating the fiftieth anniversary of the first demonstration that electromagnetic waves could be transmitted across the Atlantic Ocean, over a distance of 2,200 miles. Following Marconi's early experiments in Great Britain, wireless telegraphy was developing very rapidly at the turn of the century for short-distance communication; particularly between ships and shore. Early in 1900, Marconi applied for a British patent describing appliances for conducting what was termed 'syntonic telegraphy', in which for the first time provision was made for adjusting the transmitting and receiving apparatus to operate on the same frequency or wave-length. The investigations on what we now understand as 'tuning' the equipment were essential steps in the development of long-distance trans-oceanic wireless telegraphy; and a year later, in January 1901, communication was established between St. Catherine's, Isle of Wight, and the Lizard, Cornwall, a distance of two hundred miles. Prior to this achievement, however, Marconi had already decided to make a serious attempt to send electric waves across the Atlantic; and he had enlisted the services of John Ambrose Fleming to assist in the design and installation of a high-power spark transmitting station at Poldhu in Cornwall. The project was not without its difficulties; and, viewed from the vantage point of fifty years later, the detailed technical history is of some interest and will be found recorded in Fleming's book on "The Principles of Electric Wave Telegraphy and Telephony", the first and second editions of which were published in 1906 and 1910, respectively. Reference may also be made to a "Handbook on Radio Communication", published by the Science Museum (see *Nature*, 135, 326; 1935), and to the fact that this Museum has in its collections some of the items used in these experiments.

Fleming was responsible for specifying the electrical engineering plant to be used (having an output of 25 kW.) and for designing special portions of the apparatus for generating and controlling the, for that time, powerful radiation of electric waves it was desired to create and use. At the same time, Marconi decided on the nature of the aerial system to be erected, which originally comprised a ring of twenty masts, 200 ft. high, arranged in a circle of 200 ft. in diameter, and supporting aerial wires grouped in the form of an inverted cone.

In the early months of 1901, experiments began with the view of completing the arrangements, and numerous telegraphic tests were carried out between Poldhu and Crookhaven in the south of Ireland, and Niton in the Isle of Wight. There were various set-backs, not least of which was the wrecking of the aerial system at Poldhu by a storm on September 18, 1901. The Marconi Company, however, quickly erected two wooden masts 160 ft. high and 200 ft. apart and carrying a fan-shaped aerial of 50 wires. Within two months, sufficient progress had been made to enable Marconi to contemplate making an experiment across the Atlantic; and he left England on November 27, with his two assistants, G. S. Kemp and P. W. Paget, arriving at St. Johns, Newfoundland, on December 5.

Here again, there were difficulties associated with rough weather. The receiving station was located in a government building at Signal Hill, Newfoundland, and the aerial was supported in the first place by a balloon. This was, however, lost on its first ascent, and was replaced by a large kite carrying an aerial wire which was successfully flown to a height of 400 ft. The rise and fall of the kite in the wind caused variations in the capacity of the aerial, and this precluded the use of any of the syntonic receiving apparatus which was then available. The apparatus actually used was simply a self-restoring coherer in series with the aerial and a telephone earpiece.

By prior arrangement, confirmed by cable, a daily programme of transmissions which consisted in sending the letter *s* (three successive dots in the Morse code) began on Wednesday, December 11. These signals were received and recognized on the following day, December 12, at 12.30, 1.10 and 2.20 p.m., and again at 1.38 p.m. on Friday, December 13. In this way, the fact was established that, contrary to the expectations and predictions of some theoretical workers, these electromagnetic waves could be transmitted and successfully detected around a considerable fraction of the curved surface of the earth.

The achievement created an immense sensation in every part of the civilized world, although, of course, there was much to be learned concerning the laws of propagation of radio waves and the influence of the ionosphere as we know it to-day, before communication sufficiently reliable for the transmission of coherent messages could be attained. This accomplishment was the starting point of the past fifty years of development leading to the vast and complex network of communications, broadcasting and navigation services in use to-day.

In December 1902, the Poldhu station began the first trans-Atlantic wireless telegraph service; and with various modifications from time to time this service continued until June 10, 1922, when Poldhu was finally closed for public transmissions. After that the station was used by C. S. Franklin in his experimental work with Marconi on directional short-wave transmission. Poldhu was dismantled in 1933; to-day a memorial column of granite marks the site, and inscriptions on three of the four plaques on its sides summarize the achievements described above. The fourth plaque records that "The site of this column and some six acres of land on the edge of these cliffs together with the cliffs and the foreshore beneath them were given to the National Trust in 1937 by the Marconi Company to commemorate the pioneer work done at the Poldhu wireless station between 1900 and 1933 by its research experts and radio engineers".

In concluding this article, reference may be made to another milestone in the development of radio communication across the Atlantic. This occurred twenty years later almost to the day, when, on December 9, 1921, signals were successfully received in Great Britain from twenty-seven amateur transmitting stations in America operating on wave-lengths between 200 m. and 375 m., some using spark and some continuous-wave equipment. These wave-lengths may be compared with that of about 1,800 m. used at Poldhu, and may be regarded as an intermediate step in the development of the short waves (10–100 m.) which are now used for the bulk of the world's long-distance radio-communication and broadcasting services.

OBITUARIES

Mr. William E. Heath

THE sudden death on October 25 of Mr. William E. Heath, reader in agricultural economics and vice-dean of the Faculty of Agriculture and Horticulture of the University of Nottingham, was a heavy loss to agricultural economists in the United Kingdom. Although only forty-five years of age, he was recognized as one of the leading members of his profession.

As head (until 1947) of the Farm Economics Branch of the Department of Agriculture for Scotland, one of his main tasks was the direction of a pioneer study of the problems of marginal agricultural production. At Nottingham, his main preoccupation was the extension of the teaching and research of his Department and the development of standard measures of economic efficiency capable of application by advisory officers and by farmers. Agricultural economists should, in his view, supply the farming community with yardsticks and guide posts which would enable better use to be made of farm resources and assist advisory officers to understand the economic implications of the technical advice they give to farmers. It was also his ambition to build up a good library of agricultural economics literature, and he had recently completed exchange arrangements with every institution in the English-speaking world with an agricultural economics department.

Heath was particularly interested in problems of agricultural policy and of the most efficient utilization of those national resources devoted to agricultural production. He was regarded as one of the best informed and most inspired workers in this important field. He had recently returned from a six months visit to the United States, and as he was a member of the Council of the International Conference of Agricultural Economists his loss will be felt by many outside Great Britain.

Although lamed in youth by an attack of infantile paralysis, he bore his affliction with a courage which compelled the admiration of all who came into contact with him. He took a particular interest in the work of local young farmers' clubs, but he will perhaps be best remembered by many of his younger colleagues for the sound guidance and genuine encouragement he gave them at the start of their careers.

R. BENNETT JONES

Mr. P. A. Curry

PHILIP ARTHUR CURRY, lately deputy director-general of the Physical Department of the Ministry of Public Works, Egypt, died suddenly at Littlehampton at the age of sixty-seven. After his education at Darlington Grammar School and Trinity College, Cambridge, he joined the Egyptian Survey in 1905. During the First World War he served with the Survey Company in Egypt and Palestine and afterwards became deputy director-general of the Physical Department of the Ministry of Public Works, Egypt, from which he retired in 1939. Concurrently with this he was, first, director of the Weights and Measures Service which he started and organized, and afterwards director of Helwan Observatory. He was an excellent administrator, a very good observer and skilful with instruments. Among a large amount of very useful work were the first determinations of gravity in Egypt and the Sudan, the results of which and other work are recorded in scientific papers. He was a good friend and valued colleague, and his death will be regretted by many, both Egyptian and British. He leaves a widow, two sons and two daughters.

H. E. HURST

NEWS and VIEWS

Zoology at Birmingham : Prof. O. E. Lowenstein

DR. O. E. LOWENSTEIN, whose appointment as Mason professor of zoology in the University of Birmingham in succession to Prof. P. B. Medawar has recently been announced, was born and educated in Munich. He became assistant to Prof. von Frisch ; but when the Nazi party came to power he left Germany in 1933. Through the good offices of the Academic Assistance Council and of Prof. H. Munro Fox, he was able to resume research in the University of Birmingham, where he remained, taking the degree of Ph.D., until 1937, when he went as assistant lecturer to Exeter. In the following year he moved to Glasgow, becoming eventually senior lecturer in zoology. He combines to an unusual degree the technical skill and intense research interests of the specialist with the broad knowledge of the teacher. A most distinguished worker in electrophysiology, he has made notable use of the oscillograph to investigate the function of the vertebrate labyrinth. Initial studies, largely in collaboration with the late Dr. A. Sand, on the semicircular canals in fishes, have been followed by analysis of the gravity and vibration responses of the more delicate otolith organs. He is responsible for major advances in knowledge of the distribution of functions within this most complex receptor. The width of Dr. Lowenstein's interests are revealed by his complete revision of the volume on invertebrates in Parker and Haswell's "Text-book of Zoology". No one has lectured more widely on zoological topics to university students, and he has given courses on biology and human affairs to arts students and to adult education classes. He is equally happy as research worker and as teacher, and in both capacities he will find full scope for his great abilities in the further development of the Department of Zoology at Birmingham.

Melvil Dewey (1851–1931)

SCIENTIFIC libraries throughout the world to-day use the Dewey decimal system of classification or one of its modifications. Its originator, Melvil Dewey, was born at Adams Center, New York, a century ago, on December 10, 1851. In his youth he already displayed an enthusiasm for classification and systematization. At the age of twenty-three he graduated at Amherst College, where as acting librarian he first proposed his decimal system of classification for cataloguing and arranging books and pamphlets in a library. In 1876 he helped to found the American Library Association, serving as its secretary from 1876 until 1890 and as editor of *The Library Journal* during 1876–80. Appointed librarian of Columbia

College in 1883, he established the School of Library Economy, the first institution in the United States for the training of librarians. His welcoming of women pupils met with much disapproval, as did his questionnaire concerning their height, weight, and colour of hair and eyes, and his request for a photograph. From 1889 until 1906 he was director of the New York State Library, and he inaugurated a system of travelling libraries and picture collections. A man of boundless enthusiasm and energy, Dewey promoted the use of the metric system and was keenly interested in spelling reform. In his long and useful life this great library pioneer succeeded in making many friends and also many enemies. He died in Florida on December 26, 1931.

The Coal Industry of Great Britain

THE study of the coal industry carried out by the Acton Society Trust and published under the title "The Extent of Centralization" merits the attention of a wider field than those directly connected with the industry, for it may be said that the economy of Great Britain as a whole hinges upon coal, the most important of its natural resources. Apart from the discussion of the position of the technical specialists and the use made of them—a problem which is particularly acute in the coal industry, for reasons indicated in this study, and which is the main source of complaints of over-centralization made by men within the coal industry—the report is important as providing strong evidence against the desirability of rapid and sweeping changes by legislation or otherwise. It points out that improvements are most likely to be achieved gradually; the problems are essentially those of human relations, and what is required appears to be a series of small practical improvements which in the aggregate will eventually change the whole atmosphere of the industry. The inquiry gives a clear picture of the organization of the industry and of the system of technical and functional control in use. It indicates the impossibility of carrying out a large programme of re-equipment and redevelopment on a national scale with the fullest economy without some interference with the free judgment and initiative of local government. Arrangements for achieving these ends are largely responsible for the sense of frustration which exists at several levels of the industry and for many complaints of over-centralization. Some research may well be required in order that all such problems may be solved; and the difficult one of the status of the colliery manager, the wider implications of which are discussed elsewhere, will only be fully solved when by a process of education a more highly trained type of manager, alert enough to seek and use the best technical advice available, is readily obtainable.

Antiquity of the Australian Aborigines

AT the Brisbane meeting of the Australian and New Zealand Association for the Advancement of Science, Mr. Edmund D. Gill, palæontologist in the National Museum of Victoria, gave an address on new evidence for the antiquity of man in Australia. He pointed out that Sir Richard Owen described the extinct marsupial *Thylacoleo* from bones collected by an early settler, William Adeney, from the shore of Lake Colongulac (=Timboon), Western Victoria, beside which he lived. For more than a century this has been the classic locality in Victoria for extinct giant marsupials, *Diprotodon*, *Procoptodon*, etc., being also described from here by Owen, McCoy and others. However, it has not been known previously from what bed these fossils came, but recently this was discovered and fossils collected therefrom. A dingo jaw and a carved bone (the Colongulac Bone of earlier authors), evidences of human occupation, were also collected by Adeney, and are in the National Museum, Melbourne. The fossils from this bed are remanié, being derived from a still earlier bed. An unusual matrix and the type of preservation made it easy to recognize that the collections in the Museum from Lake Colongulac came from this horizon. Since the extinct marsupial fossils were embedded, the local volcanoes have laid down an ash-spread, and a lake has cut back the resultant tuff for a great distance so as to form cliffs in it. After that came a comparatively arid period when the lake dried up, and dunes of loess more than 50 ft. high were built from the desiccated lake floor. In this loess a fossil aborigine was found. Since the dune-building phase, there has been a pluvial period when the lake returned, cutting cliffs 25–30 ft. high in the loess; also a high-level alluvium (now incised) was deposited in the valleys of creeks entering Lake Colongulac (consequent type). The loess is considered to belong to the Mid-Holocene Arid Period and the tuff to early Holocene. The cycles of sedimentation and erosion affecting the fossil bones thus carry back into the Pleistocene. Hence there is evidence for Late Pleistocene and Middle Holocene human occupation of this area.

British Bulletin of Spectroscopy

A NEW venture in the literature of spectroscopy started this September with the first number of the *British Bulletin of Spectroscopy*. It is in the form of a four-page news sheet with notices of forthcoming events, reports of various meetings in Britain and overseas, and notes and comments on recent publications and on new experimental techniques, including a summary of recent progress on applied spectroscopy at the British Iron and Steel Research Association. The *Bulletin* is in two sections: emission spectroscopy, edited by K. Dixon and W. Ramsden; and molecular spectroscopy, edited by G. H. Beavan and W. C. Price. It has been published with the co-operation of the Industrial Spectroscopy Group of the Institute of Physics, the Photoelectric Spectroscopy Group, the Infra-Red Discussion Group and the Physical Methods Group of the Society of Public Analysts and Other Analytical Chemists. It is hoped that the *Bulletin* will mark a step towards closer co-ordination of the several spectroscopic groups in Great Britain. In the foreword, by S. D. Steele, the need is stressed for some publication to cover the many small developments in experimental technique which often fail to find their way into the major scientific journals. It is also hoped that the *Bulletin* may become a useful medium for expressing views by correspondence, which will be welcomed. It is published independently and is available to all interested at 5s. a year, post free, from the honorary treasurer, W. H. Storey, Unicam Instruments (Cambridge), Ltd., Arbury Road, Cambridge.

The Fair Isle Bird Observatory

THE second annual report of the Fair Isle Bird Observatory Trust is, like the first, a record of sound work well done. During 1950 active field-work was carried out for a period of twenty-eight weeks, the work of trapping and bird-ringing being continued by the Warden during the rest of the year. Among the field-workers were students from schools and universities, some of these making a return visit to continue observations begun in the previous year. In addition to migration news, the report contains sections on selected species, trapping and bird-ringing and ectoparasites. There is also an interesting account of the recorded breeding habits of the arctic skua, great skua, grey wagtail, lapwing and fulmar. Among other items in the report are some notes in field taxonomy, special studies of the wheatear and redwing, and a statistical account of wheatear weights. The report may be obtained from the Honorary Secretary of the Trust, 35 George Street, Edinburgh 2.

Imperial Forestry Institute, Oxford : Annual Report for 1949–50

The twenty-sixth annual report of the Imperial Forestry Institute covers the year 1949–50 (pp. 27; Oxford: the Institute, 1951). The number of students attending the Institute during the year was fifty-nine, thirty-nine being undergraduates. The record number of thirty took the final honours 'school', three obtaining first-class, seven second-class, fourteen third-class and four fourth-class honours. A new departure was initiated in the previous year of sending selected subordinate service officers from the Colonies for a special course, the satisfactory completion of which may lead to promotion. This scheme has been continued, two Nigerian forest assistants and one European forester from Uganda going to Oxford. They completed the courses creditably, and the step taken is undoubtedly a wise one, since the best forest-workers below the officer grade should, if afforded the opportunity, make efficient gazetted officers. One of the successful candidates in the above-mentioned Oxford honours 'school' was a member of the Malayan subordinate forest service, and will be the first Malayan to obtain a forestry degree and promotion to the higher service. The report is full of information; details of the Institute, the practical courses and the research work undertaken by the staff are given. It has one disadvantage: it is difficult to distinguish between Oxford undergraduates taking forestry and the officers from the Colonies taking refresher courses and so forth, particularly as regards the respective courses they are following and especially the practical courses.

Glossary of Terms used in the British Plastics Industry

A recent pamphlet, "Glossary of Terms used in the Plastics Industry" (British Standard 1755 : 1951. Pp. 59; London: British Standards Institution, 1951; 6s. net.), was compiled by the British Plastics Federation and is one of the documents being prepared by the British Standards Institution to cover glossaries of terms used in various industries. It is hoped that the Standard will be of considerable use to members of the plastics industry and will serve as a basis for discussions on an international glossary for plastic materials. The terms are grouped in sections to cover: chemistry; industrial applications; constituents; properties, including thermal, electrical and mechanical; moulding processes and other manufacturing processes such as casting, extrusion, welding and finishing. The terms listed in the sections are fully defined. An alphabetical index is a useful addition.

"Elastic Constants of Alkali Halide Crystals"

The following note added in proof to the communication by Sir K. S. Krishnan and Dr. S. K. Roy published in *Nature* of November 17, p. 869, was received too late for incorporation:

The corresponding table for the elastic constants of cæsium chloride, expressed in terms of $e^2/(16d^4)$, where d is the Cs–Cl distance in the crystal, is:

	11	12	44
s	$6\alpha' - 18\chi'$	$-15\alpha' + 9\chi'$	$-3\alpha' + 9\chi'$
ρ	$2\alpha'(\delta - 2)$	$2\alpha'(\delta + 4)$	$2\alpha'(\delta - 2)$
c	$2\alpha'(\delta + 1) - 18\chi'$	$\alpha'(2\delta - 7) + 9\chi'$	$\alpha'(2\delta - 7) + 9\chi'$

α' and χ' are defined in the same manner as α and χ respectively, except that ξ, η, ζ do not now take all integral values, but are restricted to where they are all three odd, and all three even; $\alpha' = 1{\cdot}018$ and $\chi' = -1{\cdot}08$.

Colonial Service : Recent Appointments

The following appointments have recently been made in the Colonial Service: C. W. Lynn (senior agricultural officer, Gold Coast), assistant director of agriculture, Gold Coast; A. Jackson (senior chemist, Federation of Malaya), chief chemist, Federation of Malaya; R. J. Dewar (assistant conservator of forests, Nigeria), assistant conservator of forests, Nyasaland; S. A. Child (dairy and poultry officer, Northern Rhodesia), livestock officer, Tanganyika; St. G. C. Cooper (agricultural superintendent, British Guiana), agricultural superintendent, Dominica, Windward Islands; D. J. Bettson, agricultural officer, Gold Coast; L. A. Heapy, agricultural officer, Nigeria; J. L. B. Hitchcock, probationer in agriculture, Federation of Malaya; T. E. T. Trought, entomologist, Uganda; T. G. Allan, assistant conservator of forests, Fiji; F. S. Wilson, assistant conservator of forests, Tanganyika; J. L. M. Lambert, geologist (petrologist), Tanganyika; J. Robinson, senior scientific officer (chemist), Colonial Insecticides Research Unit, Tanganyika; Miss K. F. Salmond scientific officer (entomologist), Bulk Stored Grain Infestation Research, Nyasaland; W. A. Sands, scientific officer, Termite Research Unit, East Africa High Commission; B. Steele, scientific officer (botanist), Tsetse Fly Survey, Nyasaland; B. R. Thompson, veterinary officer, Northern Rhodesia; D. C. P. Evans, agricultural officer, Gold Coast; W. P. Jaffe, livestock officer, Veterinary Department, Tanganyika; M. Z. Snihur, meteorological officer, Northern Rhodesia; D. Stephens, specialist in chemistry, Agricultural Department, Gold Coast; K. A. Watson, agricultural superintendent, Nigeria.

Ramsay Memorial Fellowships for Chemical Research

The Ramsay Memorial fellowships for chemical research for 1951–52 have been awarded as follows: L. E. Lyons, a British fellowship of £500 a year at University College, London; James Jack, a Glasgow fellowship of £500 at the University of Cambridge; Dr. K. O. G. Kutschke, a Canadian fellowship at the University of Leeds; Dr. Serafin Novoa, a Spanish fellowship at the Agricultural Department, University of Oxford; Dr. Garcia de la Banda, a Spanish fellowship at the University of Bristol; Dr. Margaret D. Cameron, a United States fellowship at the University of Leeds. These awards involve the re-establishment, with the co-operation of the Fulbright

Commission, of the United States fellowship which has been in abeyance since 1928; they also include a second Spanish Ramsay fellowship. In addition, the British Ramsay fellowship, held by Dr. E. Gelles, has been renewed for a further year, and an extension of four months has been granted to H. Mendel (Netherlands) at the University of Oxford.

The Nature Conservancy: Awards for 1951

The Nature Conservancy has announced the following awards of research studentships for post-graduate training in ecology, tenable for periods of up to three years at the universities named. *Botany*: Miss B. Blanchard (Liverpool); D. H. Dalby, Miss J. M. Laptain (University College, London); M. C. F. Proctor (Queens' College, Cambridge); R. G. West (Clare College, Cambridge); D. A. Robertson (King's College, Newcastle upon Tyne). *Palæontology*: R. E. H. Reid (University College, London). *Zoology*: R. D. Hughes (Imperial College of Science and Technology, London); J. D. Lockie (Balliol College, Oxford); A. W. G. Manning (Merton College, Oxford); D. J. Morris (Magdalen College, Oxford); H. Roberts (University College, Southampton); I. W. B. Thornton (Leeds).

Christmas Lectures for Juveniles (London)

A number of lectures for juvenile audiences, to be held in London during the Christmas holidays, are being arranged by various organizations. At the Royal Institution (21 Albemarle Street, W.1), the Christmas Lectures "to a juvenile auditory" will be given by Prof. James Gray on "How Animals Move" at 3 p.m. on December 27 and 29, 1951, and January 1, 3, 5 and 8, 1952; the fee for these lectures is: juveniles £1, adults £2. The Institution of Civil Engineers (Great George Street, S.W.1) is holding three lectures, for boys 13–17 years of age, on "Exploring for Oil", "Transporting Oil in Peace and War (Pluto)", and "Working of an Oil Refinery", to be given at 3 p.m. on December 28 and 31, 1951, and January 2, 1952, respectively. The Royal Geographical Society (1 Kensington Gore, S.W.7) is arranging a lecture, "Jumbos and Jungles", and a sound film, "Scott's Last Expedition", to be given at 2.30 p.m. on December 28 and 31, respectively, for which application should be made before December 14. At the Institution of Electrical Engineers (Savoy Place, W.C.2) the sixth Christmas lecture of the Institution will be given twice, at 3 p.m. on January 3 and 4, 1952, the subject being "Electricity in Civil Aviation". The Royal Photographic Society (16 Princes Gate, S.W.7) is holding three lectures at 3 p.m. on December 31, 1951, and January 1 and 2, 1952, on "How a Lens Forms an Image", "Three-Dimensional Films", and "The Miracle of the Photographic Emulsion", respectively. In addition, the London County Council is holding twelve lectures on various subjects which will be given in different parts of London between December 31, 1951, and January 4, 1952; applications should be made through the pupil's school.

Scientific Advisers for Civil Defence

The Home Secretary has announced that the following men of science have been appointed, in a voluntary capacity, to advise on civil defence in the regions indicated: *South Western Region* (*Bristol*): senior scientific adviser, Prof. W. E. Garner; scientific advisers, Prof. S. H. Piper and Prof. F. H. Newman. *Midland Region* (*Birmingham*): senior scientific adviser, Prof. H. W. Melville; scientific advisers, Prof. P. B. Moon and Prof. J. R. Squire. *London Region*: senior scientific adviser, Sir Charles Ellis; scientific advisers, Prof. W. V. Mayneord and Dr. H. N. Rydon. *North Midland Region* (*Nottingham*): senior scientific adviser, Prof. L. F. Bates; scientific advisers, Prof. L. Hunter and Dr. D. O. Jordan. *Northern Region* (*Newcastle upon Tyne*): senior scientific adviser, Prof. W. E. Curtis; scientific adviser, Prof. G. R. Clemo. *North Eastern Region* (*Leeds*): senior scientific adviser, Prof. F. W. Spiers; scientific advisers, Prof. W. Bradley and Prof. W. Sucksmith.

Announcements

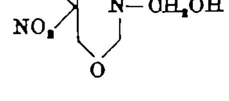
Sir David Brunt, professor of meteorology in the Imperial College of Science and Technology, University of London, has been appointed to the Board of Directors of the Fulmer Research Institute, Stoke Poges, Bucks. The Institute was founded in 1946 on the initiative of Colonel W. C. Devereux, chairman, and opened officially by Sir Stafford Cripps, then President of the Board of Trade, to carry out sponsored research, the results arising therefrom (including patents) belonging solely to the sponsors.

Dr. D. J. E. Ingram, of New College, Oxford, has been appointed research fellow in the Department of Electronics, University College, Southampton, with effect from January 1, 1952. He will be mainly concerned with the work on microwave spectroscopy which is being carried out at the College.

The conference this year of the Universities of Great Britain and Northern Ireland, convened by the Committee of Vice-Chancellors and Principals, will be held in the William Beveridge Hall, University Senate House, London, W.C.2, during December 14–15. There will be three sessions, as follows: "The Procedure for the Selection of Students for Admission to the Universities", "Universities and the Fine Arts" and "Student Health". The conference is only open to delegations appointed by the universities and to specially invited guests. Further details can be obtained from the secretary, Dr. J. F. Foster, at 5 Gordon Square, London, W.C.1.

An account is given on p. 975 in this issue of the Building Research Congress, 1951, which took place in London during September 11–20. The papers presented at the Congress have been printed in three paper-covered books, one dealing with each Division of the Congress. Copies of these books are now available, price 22*s*. 6*d*. each, or 60*s*. for the set of three, from the Organizing Secretary, Building Research Congress, 1951, Building Research Station, Garston, Watford, Herts. The price is reduced in the case of members of bodies which participated in the Congress.

Erratum. In the communication by Prof. T. Urbański entitled "New Derivatives of Nitroparaffins and Antitubercular and Antirickettsial Properties" in *Nature* of September 29, p. 562, formula (III) was incorrectly written; it should be:



DEGRADATION OF DEOXYRIBONUCLEIC ACID BY A 'NITROGEN MUSTARD'

By Dr. J. A. V. BUTLER, L. GILBERT, D. W. F. JAMES and W. C. J. ROSS
Chester Beatty Research Institute, Royal Cancer Hospital, London

IT has been shown[1] that, when treated with certain compounds of the 'mustard' type, deoxyribonucleic acid is degraded, the molecular weight as determined by measurements of sedimentation and diffusion falling from an apparent value of c. 10^6 to values between 10^4 and 10^5. The significance of this has been doubtful owing to uncertainty as to the structure of the nucleic acid and whether the molecular weight represents an aggregate or a single polymeric molecule. If the former, the low values obtained after the treatment might be due to its dissociation into the component units, when modified by the reaction. This possibility was supported by observations given in a previous communication[2]. However, new facts have been observed which are difficult to account for on this hypothesis, and support fairly directly the idea that the degradation is due in part to the breakage during reaction of the polymeric nucleic acid chain into smaller units.

The values determined of the molecular weight of the degraded nucleic acid have varied very widely, and in experiments made to ascertain the causes of the variation we made measurements of the sedimentation constant at intervals during the reaction with $CH_3—N(CH_2.CH_2.Cl)_2$ (I) and afterwards. It was found that when the reaction medium was $N/10$ sodium bicarbonate (pH 8·6) the sedimentation constant continued to decrease (see table) for a considerable time after the reagent has lost its reactivity and eventually reached a value of s_0 = c. 3. In a phosphate buffer (pH 7) the change was less extensive; but a decrease continued for several days. It appears from this that the decrease in molecular size of the nucleic acid continues after the reagent has been completely hydrolysed. The effect of pH suggests slow hydrolysis of the original reaction product, giving rise to comparatively small fragments of the original nucleotide chain. The final molecular weight observed in one case has been as low as 17,000. This very slow breakdown may, of course, have nothing to do with the original effect of the nitrogen 'mustard' which causes the loss of the viscosity.

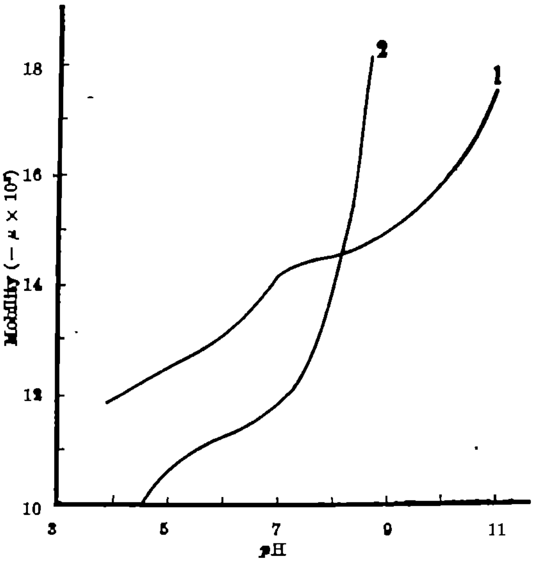
Sedimentation Constants (extrapolated to zero concentration) of Deoxyribonucleic Acid after Treatment with 'Nitrogen Mustard' (I)

In 0·1 *N* sodium bicarbonate	s_0	In phosphate buffer (0·1 *M*) pH 7·0	s
Original nucleic acid	15·8	Original nucleic acid	12·3
5 days after adding (I)	7·5	4 days after adding (I)	10·7
7 " " " (I)	6·1	6 " " " (I)	10·0
18 " " " (I)	4·6	7 " " " (I)	9·3
18 " " " (I) and freeze drying	2·2	14 " " " (I)	5·4

Information about the initial action has been obtained from the electrophoretic mobilities of nucleic acid as determined in the electrophoresis apparatus at intervals after the start of the reaction in a phosphate buffer at pH 7, and in each case giving the solution 6 hr. dialysis against the buffer with constant stirring to remove the dialysable hydrolysis products. No significant change of the electrophoretic mobility was found to accompany the loss of viscosity or to occur afterwards. The accompanying graph shows the electrophoretic mobilities of a nucleic acid treated with 'nitrogen mustard' over a range of pH's. The values of the mobility are not greatly different from those of nucleic acid.

This preparation contains about one 'mustard' residue per tetranucleotide[3], and it was expected that the mobility would be appreciably reduced owing to the partial neutralization of the charge of the nucleate ion. The *effective* charge for unit mass given by $ne/M = \mu(1 - V\rho)/s$, where μ is the electrophoretic mobility and s is the sedimentation constant, is in general not reduced by the reaction and may under some conditions be increased. This *effective charge* is not, however, easily related to the total charge of colloidal anions, and in the case of *nucleates* it has been shown that the migrating particle contains many gegenions[4]. It would appear, therefore, that the partial neutralization of the charge of the nucleate ion is partly compensated by a decrease in the number of gegenions carried along; that is, those mustard 'residues' which react with the phosphate groups are effectively taking the place of gegenions, so that the effective charge is not decreased. It may, in fact, be increased by this process, because the forces holding the gegenions are the electrostatic attractions of the charged phosphate backbone, and the neutralization at intervals of these phosphate groups by mustard residues will diminish the concentration of charge density on the anion as a whole and so decrease the relative number of gegenions held to the remainder.

If this picture is correct, it is difficult to account for the complete loss of viscosity as a consequence of the *partial* neutralization of the charge by the mustard residues. The partial neutralization of colloidal polymeric ions which form statistical coils, as shown by the theoretical considerations of Kühn[5]



Mobilities of thymonucleic acid: (1) untreated (data of Creeth, Jordan and Gulland (ref. 4)) and (2) after treatment with compound (I) (descending limb of U-tube) and the experimental results of Fuoss[6] and others, produces a decrease of viscosity; but a nearly complete neutralization of the charge would be required on this basis to give rise to such low viscosities as are observed with 'mustard'-treated nucleic acid. The electrophoretic experiments show that a complete neutralization has not occurred. We conclude, therefore, that these very low viscosities are produced in part at any rate by some other factor. The very low molecular weights observed with the final product suggest that some breakage of the nucleotide chains occurs in the reaction. It is at present uncertain what the molecular weight is immediately after the completion of the reaction, and experiments on this point are being made. A small number of breaks and the consequent reduction of molecular weight of the particles would have a great effect on the viscosity. If the original nucleic acid consists of rod-shaped particles of molecular weight of the order of 10^6, only a few breaks would be required to reduce the viscosity considerably, although other effects of the partial neutralization would also occur.

With regard to the mechanism of such a process, a possibility which is being explored by one of us (W. C. J. R.) is that the tri-substituted phosphate esters produced by reaction with mustard residues of the doubly esterified phosphate groups of nucleic acid are unstable. It has been shown that tri-alkyl phosphates are often less stable than the corresponding di-esters[7], and that the ease of hydrolysis depends to some extent on the nature of the alcohol component. It may therefore happen that the attachment of a 'mustard' residue to the di-esterified phosphate groups present in nucleic acid may result in a preferential hydrolysis of one of the phosphate-sugar links. Experiments are being made on the relative stabilities of di- and tri-phosphate esters derived from radiomimetic compounds to test this hypothesis.

This investigation has been supported by grants to the Royal Cancer Hospital and Chester Beatty Research Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service. PEOPLE AT WORK

THE sixth Present Question Conference was held at Lady Margaret Hall, Oxford, during April 1950. The theme discussed was "People at Work" and brought together individuals from industry and many other walks of life. A report of the addresses and discussion on this extended form of joint consultation in industry has been published in three successive issues of the journal *Question*, the last of which has recently appeared.

The first paper was given by John A. Mack, Stevenson lecturer in citizenship in the University of Glasgow, who discussed the reasons why work has become separated from the rest of life. In primitive societies there is no separate word for work and it is accepted as part of the pattern of living. In industrial communities it is something for which incentives are required, an unnatural condition in a more primitive society; human beings in industry are revolting against a system devised exclusively in response to economic and technical requirements. Originally Mack believed that the root of industrial trouble was in the workers' resentment of arbitrary authority. Investigations in many types of firms have convinced him that this is not so. In one factory where production processes are constantly being changed there is considerable stress, not because of the monotony of mass production, but because of the too frequent absence of monotony; strain is the result of the never-ending sequence of minor changes in machines and operations which results from the continuous ingenuity of technical rearrangement. In this factory there would be little point in changing the inter-personal and inter-group relations unless machine processes are reconstituted so that personal strain is eliminated; the machine must be made to fit the man and not man the machine.

This factory example demonstrates the more general conflict between organization and personal integrity in our industrial society. Modern industrial society is activated by two dynamic aspirations. One is to develop the earth's material resources so as to liberate mankind from the curse of poverty. The other is to develop the spiritual resources of the human world by the liberation of personality from the inhibitions of class, and caste, and male domination—from domination and oppression of any kind. The first is partly realized in an economic and industrial system of great ingenuity and power. The second is also realized in part. But the cost of progress has brought the evil of the disruption of what may be called a natural community. Fortunately, people are becoming aware of what is happening and human situations are arising which work against disruption.

In the second address Dr. J. H. Oldham considered the theme of industry and modern society. To-day, it is recognized that our technical, industrial society is involved in a fundamental crisis. The values in which men have believed and lived by for two thousand years have, for an increasing number of people, lost their authority and power of appeal. Industry, too, is involved in a crisis, and has to face the question whether an industrial society can produce and nourish the human qualities which are needed for maintaining society in a state of health. No technical advances, no improvements in organization, not even greater justice in the distribution of the proceeds of industry, will avail anything if the human material on which, in the last resort, everything depends, is inferior in quality. The crisis in which society and industry are alike involved to-day is fundamentally a crisis of men. Industry cannot solve its own problem unless the other forces in society are working in the right direction and lend it support; society cannot solve its crucial problem unless industry plays its part in that solution.

The fundamental cause of the crisis both in society and industry lies in the belief that the whole of life can be mastered by human understanding and that everything is calculable. Man's triumph over Nature has become his enslavement—the enslavement of man to apparatus, technics, mechanization, organization, the division of labour and centralization. In industry this has been carried to its furthest limits, and economic and technical considerations have ruled out the consideration of man as a human and social being. With Prof. Rosenstock-Huessy, Oldham agrees that the working of the shift system and payment by the hour are both practices which sever man's work from his personal life. The fundamental problem is to find a place for man in an industrial and economic order inescapably subject to technical requirements and natural laws. Man must be helped to gain his self-respect and his sense of relationship, and industry has an indispensable part to play in this re-creation. Happily there is increasing evidence that industry is becoming aware of its human responsibilities and in some ways is already beginning to work out a type of society which is neither individualistic nor collectivist but social, and in which it is accepted that human values are more important than the technical.

Sir Wilfrid Garrett considered the role of work as education, and at first discussed the effects of his first job in industry on a boy who has recently left school. According to Sir Wilfrid the boy finds himself in an environment where he is required to serve a purpose irrespective of what he feels he wants. To help the boy in his confusion industry has to break up its often vague largeness into manageable parts which can be grasped by the individual; the production managers have to realize that they are dealing with human beings. In the case of the young people themselves they should be made to feel that however small a part they play in the industrial machine it is never without meaning because it always serves the good of the community.

Work is also teaching industrial workers at all levels the value of co-operation; and, while there may be need for less craftsmanship in industry, men and women in charge of complicated machines are proud of their charge and the products they produce in relation to the whole. Sir Wilfrid also described the educative value of various training schemes in industry and those organized for industrial workers by such organizations as the Outward Bound Trust, Brathay Hall, and the Young Men's Christian Association.

He was followed by Sir George Schuster on the theme of human relations and production, who stated that what is chiefly needed is the application of already existing ideas; the main practical problem is to get those unprogressive elements in British industry—about 90 per cent—to accept the principles and practices of the others. In the nationalized industries, particularly, the study of human relations should be regarded as a matter of vital importance: in general, one of the grave issues of the post-war world is the moral disintegration which has affected other countries in Europe more than Britain. Another difficulty is that the workers still carry bitter memories of their oppression over a period of more than a hundred years. Nor has educational development kept in step with material development. With Rostovtzeff, Sir George speculates whether it is possible to extend a higher civilization to the lower classes without debasing its standard and diluting its qualities to the vanishing point? "Is not every civilization bound to decay as soon as it begins to penetrate the masses?" Britain has not yet evolved a satisfactory pattern of an educated and democratic industrial society. If human relations in industry are to be satisfactory, three essential conditions must be fulfilled. First, each individual must be treated as an end in himself, and not as a means to an end. Secondly, he must be given the basis for the good life, including his status in society. Thirdly, the individual must recognize that he can only realize himself satisfactorily as a member of a community. Nor can any man lead a good life unless he is doing a good job of work despite those conflicting loyalties born of an industrial society. Here joint consultation properly interpreted is an essential condition for establishing the right kind of human relationships in industry. Nor can 'loyalty' be expected unless the individual really accepts the belief that he 'belongs' to the firm.

Prof. C. A. Mace considered under what conditions work may be made not only more effective but also a source of greater satisfaction to those who do it. In general, work is not attractive or repulsive because of any particular feature in isolation; it depends upon the pattern of the work as a whole. It is not repetition or variety that matters but the ratio of repetition to variety. Everyone needs the element of adventure or risk against a background of fundamental security. In industry to-day there is a lack of balance, a lack of individuality, the worker feeling deprived of the sense of responsibility for an individual task. The new industrial order can be created only by slow progressive stages, taking each job one by one, and by the gradual development and application of new principles, new policies and new procedures of management. Sufficient evidence is already available to show that sub-division, standardization and simplification have been overdone and that efficiency and satisfaction in the job will be enhanced by a reversal of these trends.

To help in understanding how people work in industrial societies, Prof. S. F. Nadel addressed the conference on work in relatively simple, pre-industrial and pre-literate societies. In these primitive societies men mostly work on their own, the typical use of capital, whereby certain individuals pay for the services and efforts of others, being largely unknown. Nor, in primitive societies, do people work so that they may enjoy pursuits out of work; their enjoyments are often so directly connected with the work and its results that the completion of the job, its reward, and the desired enjoyments merge into one.

One important and widespread incentive in primitive societies lies in the work itself. In settled agricultural communities the people always attach great importance to the attractive lay-out of the farms; anthropologists have long been struck by the great importance of display in primitive economy, the chance of displaying success probably acting as the strongest incentive to work. Behind the activity of most individuals is the wish to attain prestige or to win the admiration and approval of others. In other societies where there is a choice of work, like weaving or leatherwork, the individual conceives of his work as being in some measure the concern of supernatural powers. For each individual work is a duty which he does not question, rooted in religious belief and buttressed by the idea that it has been vested in his family or line of descent since times immemorial. For primitive man work may be regarded as a 'passport', if not to social excellence, at least to the fulfilment of an ethical or religious code.

In discussing motivations and the effects of motivation on productivity, Mrs. Winifred Raphael suggested that productivity is an attitude of mind. When there is not a strong motivation to work, there is poor output and high labour wastage; there is also boredom and discontent. Whether a person is bored or interested in his work depends upon whether he is properly suited to that work; some people are suited by supervisory jobs, and others are most happy when doing apparently dull, routine, mechanical jobs. To be properly suited all individuals should be helped to find the right job when they leave school and, later, in any change they make; and, when labour is short, it is most important to use the labour force to the best advantage. It was Sir Walter Raleigh who said, "The nightingale did not win a prize in the poultry show"; a real attempt must be made to match the person to the job and the job to the person. Boredom or interest will also depend upon the extent to which the individual participates in the affairs of the firm; this may be encouraged by formal and informal joint consultation. Interest also depends upon the social environment and, for many people in industry, what matters most is neither the job nor the pay but the people they are working with; workers' solidarity is one of the strongest motives in industry.

Probably, however, the greatest effect upon motivation depends upon whether an individual feels he is being fairly treated; pay is always thought of in relation to other individuals. Another factor affecting motivation for or against work is whether individuals are repressed or encouraged; pride in the job is an important incentive. Training is also important since the individual feels that opportunities for training may lead to promotion.

After discussing motivating forces in general, Mr. E. W. Hughes advocated the use of intelligent rather than sentimental control of the prime urges to action. Among the more permanent incentives he regarded the need to satisfy self-expression through some activity as one of the most important, especially if the effort is recognized by the group in terms accepted by the group. Mr. Hughes has had special experience in the mining industry, and here, although many motivation problems are similar to those of other industries, the industry still has a long leeway to make up in certain conditions of work. But the effort is being made, and the National Coal Board is making a genuine and not unsuccessful attempt to remove factors which cause accidents, the stigma which goes with dirty faces and dirty clothes, and other deterrents. At Keresley Colliery, near Coventry, for example, the surface lay-out is such that, but for the pit-head gear, the colliery could be mistaken for a light engineering factory. In South Wales the casualties caused by dust resulted in a drift from the industry. The dust problem has been energetically tackled, and miners are returning to the industry.

Among the reasons why people enter the coal-mining industry is security of tenure. This is particularly true of young men and, for them, various apprenticeship and training schemes have been devised. Good wages have not the incentive value usually described, as is shown by the reduction of the mining labour force despite considerable increases in pay. Mr. Hughes also expressed the need for an extended system of joint consultation at horizontal levels in the mining industry.

In his address on organization and the person Mr. R. W. Latham suggested that joint consultation is not consultative procedure but an attitude of mind. Nor is it new despite the official introduction of joint consultation to industry by Sir Stafford Cripps in 1942; some small firms in Britain had established machinery for joint consultation in the eighteenth century. Mr. Latham also pleaded for the use of *ad hoc* committees in those departments of a factory which have particular problems. But he could not agree with other speakers who believed that, apart from wages negotiations, confidential matters to the firm and about individuals, nothing should be barred from discussion at works councils. According to Latham, most workers do not understand balance sheets or market research, and he advocated the education of industrial employees as one of the most urgent needs of to-day; this should be undertaken by the trade unions themselves. The majority of workers do want to participate in the activities of their firm, but, despite the clamour of a small minority, they do not want control.

In the ensuing discussion probably the most interesting point which arose concerned the profit motive and the social purpose of industry. This was summarized by one speaker as consisting of three main factors: first, it is generally accepted that private industry cannot be allowed to follow its own way without an ethical code; secondly, bureaucratic control is bad for industry because it is so negative; thirdly, there is a considerable and justifiable demand for participation in the control of industry and responsibility for running it by all who are engaged in it.

T. H. Hawkins

INDUSTRIAL RADIOLOGY GROUP OF THE INSTITUTE OF PHYSICS

SUMMER MEETING

THE summer meeting of the Industrial Radiology Group of the Institute of Physics was held at the Institute's House, 47 Belgrave Square, London, S.W.1, during July 23–25. A programme of lectures, covering a wide field of interest to the industrial radiologist, was arranged. One of the most interesting was that by Mr. L. van Ouwerkerk (Rontgen Technische Dienst, Holland), with the title "Xeroradiography", which it was explained is a dry method without the use of photographic films and is at present in the laboratory stage.

Mr. van Ouwerkerk stressed that his was largely a report of what had been done in the United States on this subject. Starting with a description of the application of xerography to photography, he described how a layer of photo-conducting insulating material, deposited on a metal plate, is charged and then exposed to light, with the resultant leaking away of the charge in proportion to the light falling on any spot. This latent image is developed by dusting with a fine powder which adheres only where the plate is charged. Prints can be made by transferring and fixing the powder image to paper. In elaborating these points Mr. van Ouwerkerk described in detail the requirements of the photo-sensitive plate as regards electrical conductivity and how it is charged under corona discharge, as well as the action of incident light in discharging it. He said that the latent image can be retained on the plate for several days, and described how it is developed by a powder mixture consisting of a fine resinous powder and a granular carrier of relatively large particle size, which serves to generate a charge on the smaller powder particles.

This powder image can be transferred to paper, plastic, material, etc., charged with the opposite sign and placed in contact with it, and is then fixed by fusing the resinous powder.

In considering the application of the method to radiography, Mr. van Ouwerkerk said that the inherent unsharpness due to grain size is better than for photographic film. Finer powders are used for development than in the case of xerography. One interesting point is that a crack in the object being radiographed gives an enhanced effect due to the localized charge there. The method has been successful with energies between 5 kV. and 10 MeV., exposure times required being somewhat less than for X-ray films. Good definition is obtained. In concluding, Mr. van Ouwerkerk said that the obvious advantages of the method make it merit our attention in the future.

In opening the discussion on Mr. van Ouwerkerk's paper, Mr. D. T. O'Connor related his own experiences with xeroradiography. The materials are inexpensive, the main difficulty being the selenium-coated plate, produced by the vacuum coating technique. For charging the plate almost any material is suitable, such as powdered charcoal, the cloud method being the simplest process. In this the powder is blown through a tube by means of compressed air into a box containing the plate. Mr. O'Connor spoke of the high cost of X-ray films for radiography and of their possible scarcity. Mr. van Ouwerkerk said that some loss of sensitivity is unavoidable in making permanent records by fusion of the sprayed powder ; but it should be possible to compensate for this to some extent by increasing the contrast in copying. The only limitation in the size of the plate is in obtaining a uniform coating of selenium. Metal intensifying screens must, of course, not be in metallic contact with the plate, but this does not appear to cause loss of definition. He agreed that atmospheric humidity may cause some loss of charge of the plate.

One morning session was devoted to a symposium on "Penetrameters", and in introducing this Mr. J. C. Rockley (Aeronautical Inspection Directorate, Harefield) stated that a wider use of these is desirable ; but that guidance is needed in their correct use, since the results obtained from different types do not always agree. He said that the function of the penetrameter is that of quality control, and in his opinion the step type gives a good idea of sensitivity and contrast, while the wire or ball type gives an idea of definition. He concluded with some remarks on deciding the position of the penetrameter on the specimen.

The principal speaker in the symposium, Mr. B. Schuil (Röntgen Technische Dienst) started by criticizing the name 'penetrameter', since the device neither measures nor expresses any quality in accepted units. penetration cannot, he claimed, be measured by expressing it as thickness-sensitivity, that is, the percentage of the wall thickness indicated by the last visible step or wire, since this depends on both geometry and exposure technique. A true penetrameter should compare the intensity of radiation after passing the object with that of the primary beam. In asking why we use penetrameters, Mr. Schuil said that their use means getting the best penetrameter image as regards contrast and definition. He gave as an example a case in which, by using salt screens instead of lead screens, a higher sensitivity was obtained due to greater contrast, in spite of the poorer quality image. But an optimum penetrameter image does not, he maintained, guarantee a sound object ; many other factors influence the detection of flaws. Again, with very hard radiation, the absolute flaw sensitivity increases, and it is not possible to express it as a percentage of the plate thickness ; rather, a certain minimum thickness can be revealed. Regarding different types of penetrameter, Mr. Schuil said that there is no ideal form, but he prefers, in general, those using wires to those using step-wedges or test plates, such as are recommended by the boiler code of the American Society of Mechanical Engineers. He concluded with some remarks on the practical use of penetrameters and the ideal penetrameter.

In opening the discussion on penetrameters, the chairman, Mr. C. Croxson (Armament Research Establishment, Woolwich), pointed out the advantages of having separate checks for definition and contrast, as embodied, for example, in the Ministry of Supply penetrameter. As a check on definition he suggested (*a*) fine wires of material similar to that of the specimen for use with small thicknesses, and (*b*) drilled holes in a plate, of similar material to that of the specimen, about 0·02 in. in diameter and of minimum depth to give just perceptible images ; the latter for use with thick specimens. Mr. O'Connor said that a test object of comparatively large area is needed to assess contrast, and one of small area to assess definition. He expressed no particular preference for the step wedge type over the strip type used by the American Army Ordnance. Dr. A. Nemet pointed out the interrelation of contrast and definition; and while Mr. Croxson agreed, he said that nevertheless a more sensitive penetrameter can be made by having separate checks for the two, as he had suggested. Mr. E. Owen (Hadfields, Ltd.) said that he has found that the ball type of penetrameter has the poorest sensitivity. Other points made were the desirability of an identification mark as an integral part of a penetrameter ; the necessity for a robust inexpensive construction ; and the desirability of flexibility for penetrameters to be used on curved surfaces. The comments appeared on the whole to favour the wire type of penetrameter, but it was evident that it is as yet premature to consider the standardization of any particular types.

At further sessions Mr. D. Bromley (Admiralty Materials Laboratory, Poole) spoke on "An Analysis of the Quality of Radiographs", Mr. J. Rhodes (Royal Ordnance Factory, Woolwich) on "Gamma-ray Stereography", and Mr. H. Vinter (Denmark) on "The Correlation of Radiographic Results with Weld Strength". A comprehensive paper describing non-destructive testing in Germany was read for Prof. R. Berthold (formerly of the Reichsröntgenstelle, Berlin) in his absence, and Mr. E. van Someren (Murex Welding Processes, Ltd.) gave a paper entitled "Short Range Radiography". The meeting concluded with a symposium on "The Site Radiography of Pipe Welds", at which Mr. F. H. Gottfeld (Solus Schall, Ltd.) and Mr. R. V. Walker (Ministry of Supply) were the principal speakers.

An exhibition of apparatus of interest to the industrial radiologist, arranged by Mr. J. C. Rockley, was held concurrently with the summer meeting and comprised six sections. The first illustrated radioactive materials in industrial radiography and showed, as an example, the construction of a radiographic source containing radon and the extraction of the necessary radon. Further exhibits showed containers for gamma-ray sources and devices for handling them, a total of nine exhibits. Six of these were available commercially, and the remainder had been designed by individual radiologists to meet their own needs. Protection was covered in this section by a selection of portable monitors, dosemeters and film badges suitable for workers with gamma-rays. Further exhibits showed the lay-out of X-ray laboratories by means of a model and photographs, as well as samples of many of the protective materials on the market. A section of outstanding interest showed by means of specimens the development of X-ray tubes from 1896 to the present day, mostly loaned by Messrs. Newton Victor, Ltd. In a section devoted to special applications of X- and gamma-rays, interesting examples were those on the use of X-rays in micro-radiography by the Bristol Aeroplane Co., Ltd., the autoradiography of radium and radon containers as a check on the correct distribution of the radioactive material by the Radiochemical Centre, Amersham, and electron radiographs of bank-notes taken by the Atomic Energy Research Establishment, Harwell, from the scattered electrons using an iridium-192 source. The section on stereoradiography, arranged by Ilford, Ltd., showed some striking applications of stereo work in radiography, together with examples of the apparatus required for this work. The section on radiographs covered a wide field in which twelve firms exhibited. Johnson Matthey and Co., Ltd., showed radiographs of brazed fittings, and Kodak, Ltd., had an instructive exhibit showing how gratuitous markings on the film due to various external causes can mislead the radiographer. Exhibits by the Aeronautical Inspection Directorate and the Atomic Energy Research Establishment showed the wide range of problems ranging from plywoods to wire-wound resistors that had been dealt with by these establishments. A final section showed a working model of a beta-ray thickness gauge.

B. N. Clack

EFFECT OF COLD ON MICRO-ORGANISMS

The autumn meeting of the Society for Applied Bacteriology was held in the lecture hall of the London Medical Society on October 23, when a symposium was held on the subject of "The Effect of Cold on Micro-Organisms". There were about 120 members and visitors present.

Dr. A. T. R. Mattick (National Institute for Research in Dairying) opened the symposium by a short historical survey of the subject. He described how the lethal effect of freezing on bacterial cells, originally thought to be due to the crushing mechanism of ice crystals, has now given way to the concept of protein denaturation and precipitation. This is due to the classical work of Haines in 1937, who found that freezing at temperatures between −5° and −70° C. had no effect on the mortality of *Pseudomonas* species of bacteria, but that temperature is significant for survival on storage. Between −1° and −20° C., greater death-rates were found at the higher temperature, the critical maximum being −2° C. Extending these observations further, Weiser and Osterud in 1945 emphasized the difference between immediate death caused by the action of freezing, which is independent of temperature, and storage death, which is dependent on temperature and time. Storage death-rates are lower at temperatures below −30° C. than at temperatures above this value, such that at −195° C. no deaths appear to take place.

The limiting temperature below which all organisms cease to grow is about −8° C., although many bacteria will remain viable for long periods below this temperature. For example, *Streptococcus faecalis* has been found viable in cheese after seven years at −15° C., and coliforms and *Pseudomonas* species have been found in butter. The metabolism of many bacteria is affected by reduced temperatures, the effect being largely that of change from saccharolytic to proteolytic and lipolytic action.

Dr. J. G. Davis (United Dairies, London), discussing the effect of cold in relation to dairying, said that the changes in metabolism which many bacteria undergo at reduced temperatures often give rise to pigment formation; for example, *Pseudomonas* can readily produce colour in milk and has been known to impart a blue-black pigment to butter. Probably more significant is the bitter, or sometimes 'oxidized' or oily, taste acquired by milk due to the lipolytic activities of micro-organisms. Plate counts on such milk samples may not be significantly affected; but the methylene blue test shows a marked decline. It is doubtful whether any cryophilic organisms can survive pasteurization, but obviously any which might escape such treatment will be liable to exert an adverse effect on the milk.

Ice cream of good quality can be stored satisfactorily at −10° C., at which temperature the bacterial count tends to fall; and, contrary to early opinion, cheese can be ripened at low temperatures and gives a better product free from bitter taste.

Dr. M. Ingram (Low Temperature Research Station, Cambridge), dealing with cold in relation to the microbiology of foods, said that all spoilage is due in the first place to the activities of micro-organisms. Freezing, however, is not always possible with many foodstuffs—for example, fruit and meat—and chilling only can be employed. The Q_{10} value of 2, which usually obtains in chemical reactions, is subject to much variation in bacteriology and depends very much on the species of micro-organisms being considered. It is, in fact, much higher than 2 at lower temperatures; hence a difference of only 1 or 2° C. at these levels may have a considerable effect on rate of spoilage. With all tissue material, especially the living tissues of fruit, a balance has to be sought between tissue damage or death and bacterial rot.

In general, pathogenic organisms cease to grow below about 5° C., *Bact. coli* at −5° C., and *Achromobacter* and *Pseudomonas* species at −3° C. Staphylococci and spore-forming bacteria do not suffer a high mortality on freezing, but most other types do. Mortality and storage death-rates are reduced by such substances as sugars and glycerol, and osmotic pressure plays a considerable part.

Enzyme action is not stopped by cold at anything like the same rate as bacterial growth; hence much lower temperatures are necessary for the preservation of some foods such as peas, herring and bacon.

Mr. H. Proom (Wellcome Physiological Research Laboratories, Beckenham) described some problems associated with freeze-drying. Freeze-drying for biological purposes was first described in 1909 by Shackle. Later, in 1933, Flosdorf and Mudd used a manifold process, and afterwards sublimation and spin-freezing methods were developed.

The effect of freeze-drying on the viability of bacteria varies with the species and the medium employed; but the importance of the process is in the fact that organisms so treated retain completely their serological characteristics, toxin production and other physiological properties for very long periods of time. Bacteria suspended in saline alone have a poor survival-rate; but the addition of broth, serum or gelatin exerts similar protective actions. Serum is suspect because of its hygroscopic nature and the consequent deleterious effect of moisture on the organisms.

Survival-rates after drying are dependent on a number of factors, including temperature; for example, reported comparative rates at 4° and at 37° C. are 83 per cent and 28 per cent respectively. The relationship between storage loss and time is allied to losses on heating at temperatures between 60° and 100° C., and short heatings at these temperatures can give a measure of storage survival. In spite of reports that there is an optimum small residual moisture content for maximum survival, it now appears quite certain that such an optimum is not obtained, and greatest survivals are found in the driest preparations. It is desirable also to include a suitable reducing substance to prevent oxidation, and the gaseous atmosphere under which the dried material is sealed is important. Dry nitrogen or sealing *in vacuo* gives the best survival conditions, the rates being nine or ten times better than those with oxygen or air.

Following the main papers there was active discussion and questioning, during which two comments were made on changes observed in properties of bacteria on freezing and thawing. One concerned the destruction of phage associated with lactobacilli, and the other, changes in antigenic reactions of some streptococci. Mr. Proom said this was the first evidence he had heard of any change produced by freezing, and the suggestion was made that it may be due to the high and selective death-rate leaving a residue of viable cells which might not be fully representative of the original.

In reply to other questions, Dr. Ingram said that moulds will grow readily in chill rooms, and that flowing air and reduction of relative humidity to less than 96 per cent will practically stop the growth of bacteria.

COMMONWEALTH OF AUSTRALIA SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

REPORT FOR THE YEAR 1949–50

THE second annual report of the Commonwealth of Australia Scientific and Industrial Research Organization* has been published, for the year ended June 30, 1950. The Organization, which now comprises sixteen Divisions, as well as several independent Sections and five regional centres, continues to face great difficulties in developing its research programmes because of the lack of suitable buildings, and many Divisions are working under crowded and difficult conditions. Work is proceeding throughout the Commonwealth on the mapping of soils and the determination of their physical and chemical properties. Further progress is reported in the development of spectrochemical techniques for analysing soil and plant material. Some fundamental work on the downward flow of water into soil was completed, and the magnitude of movements of water in soil due to temperature gradients investigated. Soil microbiological studies centred mainly round *Rhizobium*, the genus of bacteria responsible for the nodulation of leguminous plants, and the investigations commenced in 1947 into its establishment in field soils, have been concluded.

The general programme of work on pastures continued on the same basis as in the previous year; at Canberra three systems of grazing management were being compared on a *Phalaris* – subterranean clover pasture, and at the Dickson Experiment Station a series of long-term trials on the relation of pasture and cropping practice to soil fertility trends, and especially on the factors involved in such changes in fertility, was being initiated. An ecological survey of vegetation and pastures at Trangie, New South Wales, was nearing completion, while at Deniliquin, New South Wales, investigations have been completed on irrigated pastures; these were begun in 1949 to determine the factors involved in the emergence of pasture and forage species sown in various conditions and depths and with different treatments of organic litter and fungicides. Weed investigations have included studies on the use of plant growth-regulating substances for the control of perennial weeds, the mechanism of action of such substances, and the control of perennial grass weeds; and, besides the trials of new pasture and forage plants, investigations with linseed and other vegetable oil plants have continued. Search has been made for apple rootstocks which give better performance under Australian conditions and also for improved rootstocks for pears and plums. The general results of the opium poppy improvement programme were published during the year, and the survey of native plants for sources of substances of pharmacological value and chemical interest has been concerned mainly with the Queensland flora. The promising prospects for expanding tobacco production by irrigation during the 'dry' season in northern Australia have opened up a new field of research requiring immediate attention. Among plant disease investigations may be mentioned those on potato virus *X*, the use of plant tissue culture techniques for controlled studies of virus recovery phenomena, and the control of 'dollar spot' (*Sclerotinia homoeocarpa*) on turf by fungicides; a study of the effect of nutrition on the development of *Fusarium* wilt of tomato was concluded.

Other plant investigations are carried out at the irrigation research stations at Merbein, Victoria, and at Griffith, New South Wales, the former being concerned with the problems of irrigated horticultural lands of the middle and lower Murray, particularly the cultivation and processing of grapes, and the latter, besides studies on irrigation and soil salting, being concerned especially with the development and nutrition requirements of such crops as oranges and vegetables. Successful control of hardhead (*Centaurea picris*) with the weedkiller 'Hormex' and of hoary cress (*Lepidium draba*) with 'Methoxone' and 'Hormex' is reported.

The Division of Animal Health and Production, which has its headquarters in Melbourne, has been concerned mainly with problems in the sheep and cattle industries. Besides a further study of the nutritional factors which determine wool production, this work on sheep has included studies of the processes of rumination, the toxicity of large rations of wheat, the effect of cobalt and copper deficiencies in nutrition, the physiology of reproduction, biological studies of the growth of skin and wool, the efficacy of phenothiazine against the large-mouth bowel worm (*Charbertia ovina*), resistance to nematode infestation, and the value of DDT and BHC preparations in preventing body strike as well as tests with insecticidal fogs for this purpose. Cattle investigations have included studies on pleuropneumonia, tuberculosis and brucellosis, the value of antibiotics in eliminating udder infections, the epidemiology of parasitic gastro-enteritis of cattle; the ecology of the non-parasitic stages of the cattle tick and bio-assay tests with a number of chlorinated hydrocarbons and organic phosphates which permit the division of potential acaricides into three main classes. Other work on nutrition has embraced studies of the influence of copper or zinc deficiency on the phosphorus metabolism of Algerian oat plants in aqueous culture, on accessory food factors and on the reactions of amino-acids.

---

* Second Annual Report of the Commonwealth Scientific and Industrial Research Organization for the Year ending 30th June, 1950. Pp. 157. (Canberra: Commonwealth Government Printer, 1950.) 9s.

Some of the work which has been here noted was carried out in association with the Division of Entomology, which, besides work on various aspects of insect physiology, made an intensive field study of the control of St. John's wort, *Hypericum perforatum* L., with *Chrysomela hyperici* and *C. gemellata*. Encouraging results were also obtained in the biological control of the cabbage moth, *Plutella maculipennis*, with the ichneumonid parasites, *Angitia cerophaga* and *Diadromus collaris*. Preliminary work on population dynamics has been based on the sheep blowfly, and work has continued on the ecological control of the Australian plague locust, *Chortoicetes terminifera*, and on the distribution and ecology of the pasture cockchafer, *Aphodius howitti* Hope. The Wild Life Survey Section, established early in 1949, has been solely concerned with basic ecological studies on the rabbit, further trials of the virus disease, *Myxomatosis cuniculi*, and of poisons for the same pest (see *Nature*, Dec. 1, p. 932).

Fisheries investigations included work on the races of the Australian salmon (*Arripis trutta*), a survey of tuna resources in northern Australia, a study of barracuta in the Bass Strait area, further investigations of the properties of the deep waters off Rottnest Island, Western Australia, and continued surveys on crayfish and sand crabs. Work on pilchards is described in two papers to appear in the new periodical, the *Australian Journal of Marine and Freshwater Research*, publication of which commenced in April 1950 (see *Nature*, 166, 719; 1950). Food research included investigations on the anaerobic destruction of ascorbic acid, on the natural coating of apples and on protein denaturation. Investigation of the factors affecting the germination of heat-treated spores continued, as well as of the effects of oil and other coatings applied to the shells of eggs before storage, the variability in the storage behaviour of apples, the canning of peas, the dehydration of fruit and meat, and the drying of sultanas. Studies on the incorporation of skim milk powder in bread have been resumed and those on the chemistry of the taint in butter caused by *Coronopus didymus* continued.

Work has continued in the Division of Forest Products on wood structure in relation to properties, the chemistry of wood, creep in wood, the physical properties of wood and related materials, timber mechanics and seasoning, as well as on the toxicity and permanence of water-borne preservatives and on veneer and plywood manufacture. The status of the Building Research Section has been raised to that of a Division, and the experimental work on foamed concrete continued. Investigations on surfacing materials have included a study of the physiological effects of the thermal and mechanical properties of concrete floors, while the acoustic behaviour of rooms and halls, the suitability of bituminous membranes for flat roofs and the efficiency of the inter-layer bond of membranes of various kinds as well as the sulphide staining and growth of mould on water-paint films on fibrous plaster are all being studied. A new Wool Textile Research Laboratory was being organized in each of the three major textile centres—Melbourne, Sydney and Geelong—and studies were being made on detergency in connexion with wool scouring, the aliphatic alcohols of wool wax, the recovery of wool from skin pieces by complete digestion of the skin pieces, the application of resins to wool, the action of shrinkproofing agents on wool, the structure of the cuticle of wool fibre, and the molecular structure of amino-acids, lower peptides, synthetic polypeptides and natural fibrous proteins. In the Flax Research Laboratory efforts have been made to devise methods of carrying on the retting bacteria from ret to ret so as to avoid the necessity of inoculating each ret separately.

In the Division of Industrial Chemistry, promising results have been obtained in the refining of sugar-cane wax recovered from waste materials from the sugar mills, while a project on the utilization of brown coal provides the basic data for a programme for producing liquid fuels and organic chemicals from the extensive low-grade coals of Australia. A report on the clay resources of South Australia was in preparation, and extensive research to improve the performance of refractories, particularly for the gas and cement industries, was in progress. Other investigations include the application of surface chemistry to the study of the flotation of minerals, the kinetics of the phenol-formaldehyde condensation and the physical properties of fluids at high pressures. In the Section of Physical Metallurgy work on the strength and structure of metals has been continued, particularly on the mechanism of failure by fatigue and the influence of rate of strain on the mechanism of deformation at high temperatures; but attention has been given chiefly to the constitution and properties of alloys of titanium, the allotropy of titanium and the creep of lead alloys.

The Division of Tribophysics reports further progress in the study of friction and lubrication, and plastic deformation and phase changes of metals. The work of the Division of Metrology has been largely directed towards meeting the requirements of the National Standards Commission and so enabling the Weights and Measures (National Standards) Act, 1948, to be proclaimed. Much of the work of the Division of Physics also consisted in research on the maintenance of standards and on methods of accurate measurement. The Division also investigated the composition and temperature distribution of the solar atmosphere, and a spectroheliograph which will take photographs of phenomena such as flares and prominences on the sun's surface is being constructed. Much work has also been done on the construction of equipment for researches on the properties of matter at very low temperatures and for the measurement of the elastic properties of wool by supersonic techniques. In the Division of Electrotechnology, besides work on electrical measurements and standards, the dielectric properties of materials have been investigated with particular reference to the mechanism of dielectric loss. In the Division of Radiophysics further advance has been made in the knowledge of the radiofrequency radiation which reaches the earth from the sun, from radio-stars and from the galaxy, as well as in our understanding of the processes by which natural rain occurs; and a new programme of radio and radar aids to navigation was introduced, including microwave direction-finding and relay radar. The Organization has also been co-operating with the University of Melbourne in research on nuclear physics and cosmic rays under the direction of Prof. L. H. Martin.

LABOUR TURNOVER AND ABSENCE IN GREAT BRITAIN UNDER FULL EMPLOYMENT

IT is generally believed that rates of labour turnover and absence in Great Britain have been higher under full employment than they were before the Second World War, and constitute a substantial obstacle to industrial efficiency; but hitherto there have not been records in sufficient detail to reveal the course and causes of turnover and absence in a particular setting. Accordingly two monographs[*] published by the University of Birmingham Faculty of Commerce and Social Science—"Labour Turnover under Full Employment", by Dr. Joyce R. Long, and "Absence under Full Employment", by Hilde Behrend—are important. They report and analyse the experience of factories in the Midlands, employing between them upwards of sixty thousand persons, mostly in engineering and metal working. The collection of this material was made possible through the Midland Advisory Council on Industrial Productivity.

Each monograph sets out what evidence there is for the difference between recent working and that of the interwar years. Such evidence is scanty; but, so far as it goes, it shows less difference than common report suggests. A survey by the National Institute of Industrial Psychology[1] in 1937 gave annual turnover-rates of 18 per cent for men and 51 per cent for women in a sample of London firms, and 11 per cent for men and 34 per cent for women in a Leeds sample. Records for 1949 collected by the British Institute of Management give rates of 21–24 per cent for men, and 38–41 per cent for women. Rates vary so much from firm to firm that generalizations from samples are hazardous; but these inquiries at least show considerable overlap between the pre-war and post-war ranges. As regards absence, the only continuous record is that for the coal miners, and, though the percentage of possible shifts missed has been around 12 of recent years as against 6 before the War, Miss Behrend in her monograph shows that this is due to a rise in the number of possible shifts rather than to a fall in attendances, which remain fairly steady, now as in the interwar years, around 4·7 shifts a week.

The main finding of Dr. Long's study of turnover is perhaps that the rate of turnover depends on the type of worker rather than on the type of firm, and that some types of worker have high rates of turnover whereas the majority are stable. She calculates a stability-rate, defined as the percentage of a firm's employees who have not left it during a certain period, and finds that the same firm may have both a high stability-rate and a high turnover-rate. Herein lies much of the explanation of the negative relation which she shows has generally held between unemployment and turnover: turnover is lower when unemployment is high not because all types of labour change jobs less often then, so much as because the unemployed contain a high proportion of types whose turnover-rates are habitually high. The characteristics associated with such rates are chiefly youth, lack of skill, and coming to work from a distance. Long service may be a source of stability; but it is hard to separate this influence, for those who have stayed on will be those who were more stable initially. Women usually show higher rates than men; but much of this seems to depend on lack of skill rather than on sex, for men doing unskilled work often have rates as high as the women, or higher. By contrast with these personal factors, the conditions of employment, such as the size of the firm, the level of pay and the working environment, show no clear association with the turnover-rate, though some differences between the rates of otherwise similar groups of workers are attributable to the state of personal relations in the plants, and especially the quality of supervision.

The special contribution of Miss Behrend's study of absence is the means it proposes for measuring controllable and uncontrollable absence separately. One element of the uncontrollable part is 'unavoidable' absence due to sickness, accidents and family affairs; but Miss Behrend holds that there is a further element which likewise is largely beyond the power of management to control because it is inherent in the nature of the work and of the labour force this work attracts. A sample of daily absence-rates shows marked differences between one day of the week and another, with Friday usually the lowest, and a given plant or department seems to have a characteristic and persistent weekly pattern: Miss Behrend suggests that it should take its Friday-rate as the measure of the uncontrollable absence specific to it, and the excess of absence on other days as the measure of controllable absence (see *Nature*, 165, 831; 1950). More particularly, she proposes a 'Blue Monday' index, giving the shortfall of Monday's attendance below Friday's as an indication of the workers' attitude to their work. In a study of two companies she finds that the 'Blue Monday' index is not correlated with the total absence-rate, for this depends mostly on sickness and workers' ages, whereas the 'Blue Monday' index singles out voluntary absenteeism. This is high among short-service workers and where work is unskilled or is reckoned to impose psychological strain, but it does not seem to be associated with other working conditions.

These studies collect evidence on an important problem on which exact information has hitherto been scanty in Great Britain. Their analysis of it is thorough, suggestive and directed towards practical application. It shows how collaboration between industry and the universities in this field can yield results useful to industry.

Mutation in a Bacterial Virus

In a recent paper[1], data have been given which suggest that certain of the symbiotic bacterial viruses (bacteriophages) found in *Salmonella typhi-murium* undergo diphasic variation. The normally innocuous symbionts occasionally throw off lytic mutants which multiply actively and destroy the host bacterium. This leads to the liberation of virus particles, some of which, when brought in contact with a susceptible host bacterium, develop as symbionts and reproduce the original type of infection, while others are lytic in nature and multiply actively at the expense of the bacterium. Of the particles generated in this lytic cycle the majority are themselves lytic; but a minority—perhaps about 5 per cent— are potential symbionts. In cultures on solid medium the latter produce symbiotically infected and hence 'immune' bacteria which multiply unscathed and form the characteristic 'solid centre' of the plaque.

Another kind of mutation has now been observed which is common to most, if not all, the Group *A* phages of *S. typhi-murium*. The mutants in question can be recovered either from the supernatant fluid of a spun broth-culture of the symbiotically infected (lysogenic) strain, or from the lysate resulting from the action of these phages on an indicator strain. To detect and isolate them, a suitable dilution of either type of lysate is flooded over an agar plate sown with the indicator strain. This plate is incubated overnight. A careful search may reveal, among the characteristic 'solid centre' plaques, an occasional one showing a varying number of small granules on a clear background (Fig. 1). Such plaques may, in exceptional cases, be relatively common; but usually they are scanty, and several plates carrying many thousands of 'solid centre' plaques may be searched before one such mutant is found.

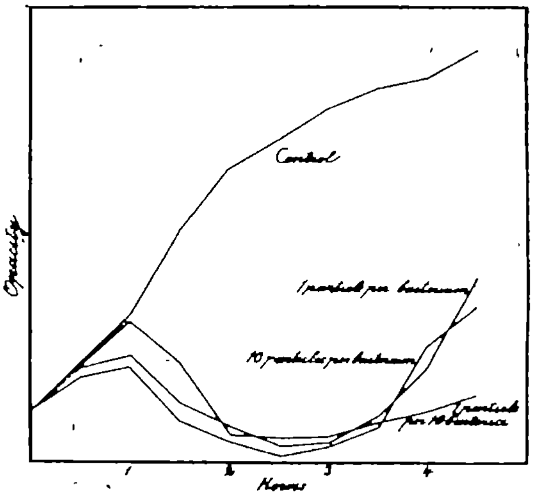

Fig. 3. Turbidity curves of cultures of phage-sensitive *Salmonella typhi-murium* initially exposed to the action of different concentrations of lytic mutant

When cultivated on an indicator strain of bacteria, these mutants in the main breed true, and show no tendency towards a general reversion to the type of particle which produces 'solid centre' plaques. Nevertheless, particles of this kind do occur, though with great rarity, in cultures of the lytic mutant, and can be identified by a corresponding technique (Fig. 2). The lytic mutants have the same antigenic structure as the strain from which they were derived, and the same resistance to heat, being able to survive exposure to temperatures of 80° C.

The organisms which make up the granules within the plaques are *not*, as in the case of the 'solid centre' plaques, symbiotically infected. The majority are phage-sensitive, and appear to exist in a state of balance with the virus. A minority are phage-resistant, and after more prolonged incubation some may be both rough and resistant. In most respects these mutants resemble the *N* phages described by Burnet[2].

The lytic character of the mutant is well shown by the turbidity curves of a growing culture of an indicator bacterium exposed to different concentrations of particles (Fig. 3). As with the familiar lytic phages, the higher the concentration of particles, the earlier the onset of lysis and clearing. This is in contrast to the curves which result when the same experiment is carried out with the parent virus where, in the presence of a high concentration of particles, no very obvious bacterial lysis occurs because significant numbers of bacteria become symbiotically infected and continue to multiply (Fig. 4), an

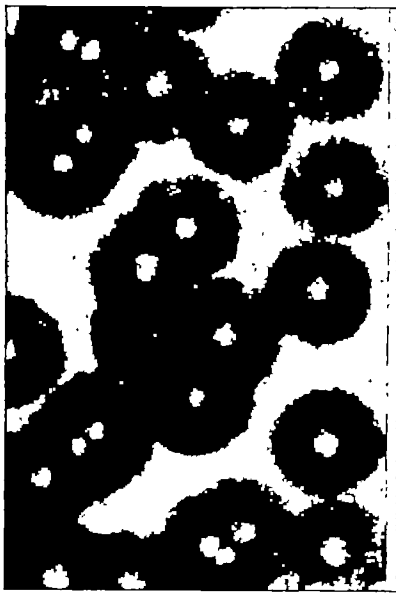

Fig. 1. Plaques of phage *A*1 showing a lytic mutant among normal 'solid centre' plaques. × 5

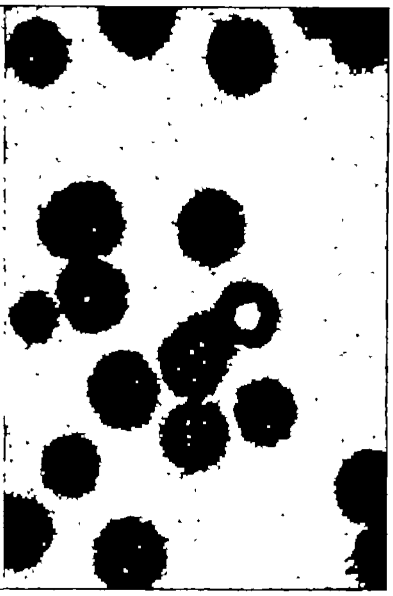

Fig. 2. Plaques from a culture of the lytic mutant showing a single 'solid centre' plaque, one of two found in sixteen plates examined. × 5

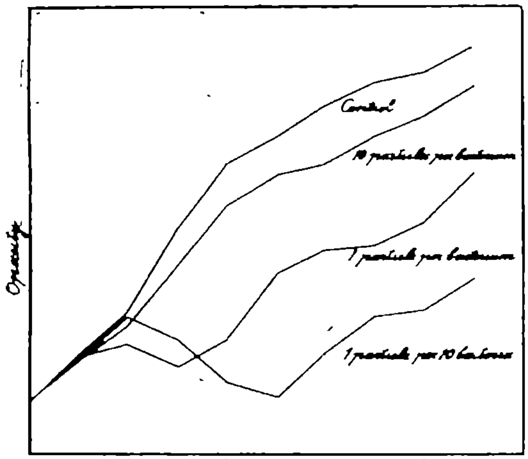

Fig. 4. Similar to Fig. 3, but exposed to virus of the type which undergoes diphasic variation, and produces 'solid centre' plaques

result which parallels the development of the 'solid centre' in the plaque.

The recognition of these stable lytic mutants is further evidence in favour of a suggestion previously made—that lytic (virulent) bacterial viruses have their origin and continuing source in innocuous parent symbionts, and represent only a single phase in the life-history of the virus.

Details of this work will be published elsewhere.

Transplantation of Mouse Eggs

The transplantation of mammalian eggs into a host uterus is usually achieved by means of an operation on the recipient female. It would clearly be of advantage in several respects if transference could be effected without the necessity of opening the body cavity of the recipient. As described below, mouse eggs transferred directly through the cervical opening into a host uterus have come to term. This seems to be the first mammal in which a direct non-operative transplantation has succeeded. It is suggested that the procedure could be called 'inovulation', by analogy with the word insemination[1].

Fertilized mouse eggs were obtained in the usual way from the uterus or Fallopian tubes of a previously mated female, sacrificed for the purpose. The apparatus (a 1-c.c. syringe bearing an obliquely blunted needle of about 0·2 mm. internal diameter), and the general procedure, were as described by Snell, Hummel and Abelmann[2] for artificial insemination of mice, except that a 4-in. needle was thought to lessen the danger of losing eggs in the lumen of the syringe. The eggs, held in the lumen of the needle in Pannett–Compton solution, were expelled into the uterus of a recipient female, the sexual cycle of which had been set into operation by mating with another male. Eggs were transferred to one horn only of the recipient uterus. Genetic marks were arranged to enable the young born of transferred eggs to be distinguished from the young of the recipient female itself (for example, transferred embryos homozygous albino, host embryos homozygous non-albino). Tested sterile males, homozygous for the dominant marker Rex as an extra precaution, were sometimes used to activate the recipient female, and the young born in two such cases were necessarily derived from transferred eggs only.

No maternal effects were observed. As scored by eye colour at birth, young from homozygous non-brown transferred eggs developed black eyes in a maternal environment homozygous for brown and pink eye; eyes which were homozygous brown developed normally in a homozygous non-brown host. In these cases, the transferred eggs and the host were all homozygous for non-agouti. In young scored a fortnight after birth, homozygous Rex and homozygous albino both showed normal expression after gestation in a host homozygous for absence of Rex and albino.

The ages of transferred eggs and recipient females were timed from the formation of a vaginal plug, with an absolute error of plus or minus a ¼-day, and the developmental stage of each egg was noted. Transplantation of fifty-five morulæ and blastulæ into recipients the sexual state of which was out of phase with the age of the eggs by a day or more, and transplantation of forty-four 1- and 2-cell stages, were unsuccessful. The five successes achieved were with morulæ and blastulæ transferred into recipients of almost exactly the appropriate sexual stage, as shown in the accompanying table. Similar optimal conditions for transfer had already been found by Fekete and Little[3], using an operative technique.

TRANSFERENCE OF MOUSE MORULÆ AND BLASTULÆ INTO RECIPIENT FEMALES OF SIMILAR AGE FROM COPULATION

Data concerning females which failed to produce any young at all are excluded. In each successful inovulation, one transferred egg per recipient female was recovered in the resulting litter

Age from copulation (days)		No. of recipient females	No. of eggs transferred	No. of transferred eggs recovered as young
Transferred eggs	Recipient females			
2¼	2	1	5	0
2½	2½	2	8	1
3	3½	1	4	1
3½	3	1	6	1
3¼	3¼	8	36	2

The present results show that eggs transferred by inovulation can come to term, but further work is necessary to establish whether the technique can develop into a routine method for egg transference.

An Electrophoresis Apparatus for analysing Several Sera Simultaneously

A SYSTEMATIC study, such as we contemplate, on the influence of disease on the electrophoresis pattern of serum, requires observations on large numbers of sera. Such an investigation is laborious and time-consuming when the available techniques and apparatus are utilized, because only a very limited number of experiments can be completed in one day. We have, therefore, devised a method whereby two electrophoretic analyses can be made simultaneously using the Tiselius apparatus with a standard central section.

The apparatus is illustrated in Fig. 1. The electrode vessels are connected on to 'Perspex' adaptors (*A* and *B*) and the standard central section of the electrophoresis cell held between them. Prior to assembly, the ground surfaces of the 'Perspex' adaptors as well as those of the electrode cell are well greased, and thin 'Cellophane' membranes are then clamped between the sections in the position indicated (M_1 and M_2). The protein solutions to be analysed are held between the membranes, and the rest of the apparatus filled with buffer and saturated potassium chloride in the usual way. The dimensions of the adaptors are such that they fit the Hilger electrophoresis bath and cell holder.

A *p*H for electrophoresis must be selected where all the components present migrate towards the bottom membrane. In the case of serum, this is achieved at *p*H values above neutrality.

In Fig. 2 are shown electrophoresis diagrams of two samples of the same bovine serum obtained simultaneously using the two limbs of the standard electrophoresis cell. On inspection of the diagrams it will be noticed that they are identical. The reason for the markedly enhanced δ-effect visible at the beginning of the electrophoresis diagram is, as yet, unexplained. In the diagram of the same serum obtained with the standard apparatus, the δ-effect was small.

Electrosmotic effects do exist; but apparently they have no effect on the electrophoresis diagram. Mobility measurements calculated from electrophoresis diagrams obtained in the modified apparatus described are likely to be affected by the electrosmotic effects, but the samples studied simultaneously are comparable.

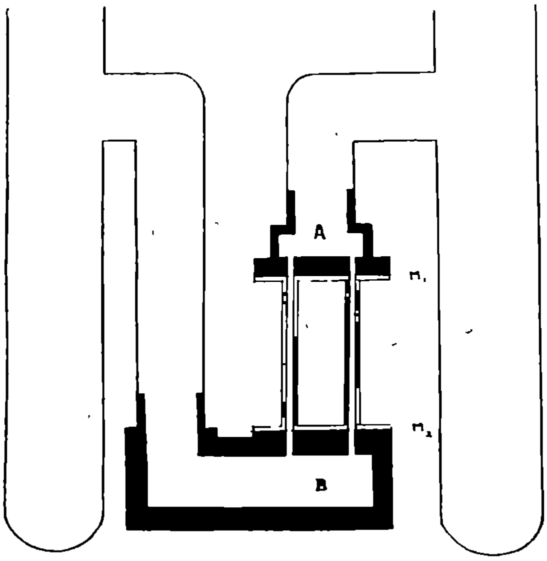

Fig. 1. Assembled electrophoresis cell. Shaded parts (*A* and *B*) are made of 'Perspex'. M_1 and M_2 are 'Cellophane' membranes

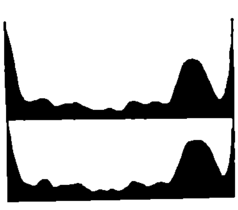

Fig. 2

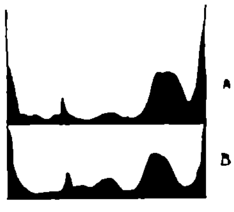

Fig. 3

Fig. 2. Electrophoresis diagrams of two samples of the same bovine serum obtained simultaneously

Fig. 3. Electrophoresis diagrams of normal serum (*A*) and serum from a chronic nephritic (*B*). They were obtained simultaneously by the use of the modified cell

The technique described points the way to a means of mass electrophoresis of sera, as there is no theoretical limit to the number of compartments which can be built into the analytical section of the cell.

A further advantage of this type of cell is that exact comparisons can be made between sera obtained from different sources. This advantage is clearly brought out in Fig. 3, which shows the difference between the serum from a normal and a chronic nephritic subject. The nephritic serum albumin has a mobility slightly less than that of the normal albumin. The α-globulin has the same mobility in both sera, and the β-globulin in the normal serum has, in turn, a lower migration-rate than the corresponding globulin in nephritic serum.

This investigation was assisted by grants from the Council for Scientific and Industrial Research and the Nkane Kitwe Poliomyelitis Research Fund.

Isolation of a Crystalline Disaccharide, Hyalobiuronic Acid, from Hyaluronic Acid

THE structure of hyaluronic acid, an important constituent of the 'ground substance', has been the subject of intensive study in recent years. Applications of conventional methylation and periodate consumption methods to the intact polysaccharide[1,2] have indicated that such methods will not yield substantial evidence of structure. The isolation and clarification of structure of crystalline oligosaccharides derived from hyaluronic acid is the most rigorous method of studying the structural details of this physiologically important substance. Such well-defined compounds are also required as models for establishing the specificity of the enzyme systems acting on hyaluronic acid.

The present communication is concerned with the isolation and characterization of a crystalline aldobiuronic acid from sodium hyaluronate in relatively high yield, following degradation by a combination of enzymic and mild acid hydrolysis. Sodium hyaluronate (analysis[3] : nitrogen, 3·78 ; uronic acid, 44·0 ; hexosamine, 38·8 ; sulphate, less than 0·5) was hydrolysed with purified testicular hyaluronidase

(600 turbidity reducing units per mgm.) until the increase in reducing sugar[4] was equal to 0·35 mgm. of glucose equivalent per mgm. of substrate. The small precipitate obtained on addition of two volumes of ethanol was removed, and the filtrate was then concentrated *in vacuo* to remove the ethanol. Addition of 4 volumes of absolute ethanol resulted in separation of a syrup, which was hardened with ethanol. The colourless, amorphous product was dried over calcium chloride and gave the following analysis: nitrogen, 2·81; uronic acid, 39·7; hexosamine, 37·9; reducing sugar (as glucose), 30·9. The yield from 1·91 gm. of sodium hyaluronate was 1·84 gm. A solution of 1·00 gm. of this product in 20 ml. of 1·0 *N* sulphuric acid was heated for 3 hr. at 99° in a sealed tube, then cooled and neutralized to *p*H 5·0 with saturated barium hydroxide. After removal of the precipitate, the amber solution was concentrated to 7 ml. and chilled, whereupon 300 mgm. of colourless material, appearing as rectangular, long prisms under the microscope, was deposited. Reheating the filtrate and washings with sulphuric acid, followed by neutralization and concentration, yielded an additional 130 mgm. Reprecipitation from 0·2 *N* hydrochloric acid solution with 1·0 *N* sodium carbonate gave homogeneous, long, rectangular prisms, weighing 232 mgm. after drying *in vacuo* over calcium chloride. The analysis of this material is presented in the accompanying table, with the values calculated for a disaccharide containing one residue of glucosamine and one of glucuronic acid.

ANALYSIS OF HYALOBIURONIC ACID

	Calc. for $C_{12}H_{21}O_{11}N$	Found
Carbon	40·56	40·01
Hydrogen	5·96	6·02
Nitrogen (Dumas)	3·94	3·99
Amino nitrogen (van Slyke)	3·94	3·96
Hexosamine	50·5	49·0
Uronic acid (gasometric)	55·2	54·3
Reducing sugar, ferricyanide[4]		68·0
Reducing sugar, hypoiodite[5]		61·0
[α, 24°, *D*] (2·00 per cent in 0·10 *N* hydrochloric acid)		+31°

Potentiometric titration indicated a substance with a pK_1' of 2·6 and a pK_2' of 7·1. On a micro hot-stage, the substance slowly decomposed without melting, beginning to darken at about 200°. The material was insoluble in glacial acetic acid, ethanol, methanol and pyridine, and almost insoluble in water. It was sparingly soluble in hot water, dilute hydrochloric acid, and dilute sodium bicarbonate. On a paper chromatogram developed by the ascending method with butanol – acetic acid – water (38 : 12 : 50) and then sprayed with *p*-dimethylaminobenzaldehyde, the material migrated with an R_F of 0·13, compared with 0·29 for glucosamine, and 0·43 for N-acetylglucosamine. The colour was identical with that given by glucosamine. The direct Elson–Morgan reaction (without preliminary hydrolysis) gave a colour value equivalent to 29 per cent of glucosamine by weight. The glucosamine residue, therefore, has a colour yield in this reaction which is only about 60 per cent of that of free glucosamine on a molar basis.

Despite the constancy of the chemical properties of all fractions examined in the course of these experiments, and the homogeneity with respect to crystal habit of the fraction described here, the analysis of this fraction by a solubility method gave results not consistent with the presence of a single species. This observation may be the result of an artefact of the analytical method, or of physical or chemical transformations which frequently occur with carbohydrate compounds. On the other hand, it may reflect the presence of two species with a structural difference due to the structure of the original polysaccharide. Further study will be required to clarify this point.

In any event, the isolated material, for which we propose the name 'hyalobiuronic acid', has the structure of a glucuronido–glucosamine with the free reducing group in the glucosamine residue. The insolubility in water must be attributed in part to the existence of the material in zwitterionic form. The stability to acid hydrolysis indicates that the glucuronic acid residue is present as a pyranoside. It is perhaps worth while to point out that hyalobiuronic acid will require re-acetylation of its amino group before a model can be obtained which will be suitable for comparison with the products obtained by enzymic hydrolysis of hyaluronic acid.

This investigation was supported by a grant from the Helen Hay Whitney Foundation.

A Brown Discoloration of Pig Fat and Vitamin E Deficiency

THE consumption of vitamin E-deficient diets rich in highly unsaturated fatty acids, by chicks and by rats, is followed by the appearance of a yellow-brown coloration of the adipose tissue[1,2]. This pigmentation can be prevented by feeding a supplement of α-tocopherol acetate[3].

In an experiment carried out at the Agricultural Research Institute (N.I.), six female pigs were given a vitamin E-deficient diet containing 5 per cent dried skim milk powder, 5 per cent dried yeast, 5 per cent white fish meal, 5 per cent liver meal, 15 per cent palm kernel meal (ext.) and 65 per cent cassava meal, with a mineral supplement of salt and limestone; the vitamin E content was less than 0·1 mgm./100 gm. In addition, two of the pigs (group *A*) received 1 oz. cod-liver oil, as a vitamin supplement, once per week from weaning until they reached 100 lb. live-weight, two pigs (group *B*) received cod-liver oil throughout, at the rate of 5 per cent of their meal ration, while the remaining pigs (group *C*) received cod-liver oil at the 5 per cent level, together with 50 mgm. *dl*-α-tocopherol acetate a head each day. The meal was fed individually to all pigs, as a wet mash, on a slightly restricted scale of feeding[4]; in groups *B* and *C* the cod-liver oil was added directly to each morning feed, and in group *C* the tocopherol acetate was added as pellets to the afternoon feed. The animals, which had been reared normally until weaning at about 30 lb. live-weight, were then all placed on the control diet; the full experimental feeding commenced at 50 lb. weight. They made satisfactory growth and exhibited no unusual external symptoms up to the time of slaughter at 210 lb. weight, after an experimental period of 120 days.

After slaughter at a bacon factory, the carcases were commercially graded, and samples of fat removed for analyses. The back-fats of group *B* were deep yellow-brown in colour and with a slightly 'oxidized' odour; the carcases were condemned as unfit for curing. The back-fats of the remaining pigs were normal in appearance and the carcases were passed through all stages of curing.

The average peroxide values[5] of whole samples of extracted loin back-fat from groups *A*, *B* and *C* were 0, 5 and 0 respectively, while the induction periods[6] were 72, 12 and 17 and the iodine values 57, 74 and 80. Determinations of vitamin E[7] gave figures of 3·0, 0 and 2·8 mgm./100 gm. Examination of the brown pigment in the fat samples from group *B* suggests that it is similar to that described by Dam and Granados[3] in connexion with vitamin E-deficient rats and chicks. Moreover, there is reason to believe that it is also related to the discoloration of carcases occasionally encountered commercially when pigs have been fed diets containing high levels of fish oils.

Cholinesterase Inhibition by Parathion *in vivo*

WE have shown[1] that OO-diethyl-O-*p*-nitrophenyl thiophosphate, an insecticidal compound generally known as parathion or *E*605, has not, when pure, any measurable *in vitro* inhibition of rat's brain cholinesterase. Nevertheless, pure parathion is a powerful inhibitor of cholinesterase *in vivo*, and there is little doubt that its mammalian toxicity is due to this property. When parathion is administered intraperitoneally to male rats (180–220 gm.) the dose necessary to produce a 50 per cent inhibition of brain cholinesterase within 30 min. is about 1·5 mgm./kgm., a figure of the same order as that required for OS-diethyl-O-*p*-nitrophenyl thiophosphate, the S-ethyl isomer of parathion, which is a highly active *in vitro* inhibitor[1]. With a dose of 3 mgm./kgm. the onset of the typical symptoms of parasympathetic stimulation occurs within 10 min. with both compounds. The cholinesterase activity of rat's blood, which is mainly due to specific enzyme in the red cells, is also unaffected by parathion *in vitro*; but *in vivo* it can readily be completely inhibited by injected parathion. There is, however, a slight but significant difference between the action of parathion and its S-ethyl isomer *in vivo*; when a dose of the former, which produces complete inhibition, is administered intravenously, there is a lag of a few minutes before the inhibition develops, whereas with the same dose of the latter the inhibition reaches completion very rapidly after injection.

These observations lead to the hypothesis that parathion undergoes a change to an active inhibitor after injection, and in confirmation of this it has been found that rat's blood may readily be inhibited by parathion *in vitro* in the presence of liver slices or homogenate. For example, 5 ml. heparinized whole blood was incubated at 37° C. with 2·5 gm. liver slices and 0·0056 ml. parathion solution (1·5 per cent in ethanol), added by means of a micrometer syringe; the cholinesterase activity of the blood was completely inhibited within 10 min. The presumed metabolite must be very unstable in blood, for if inhibited blood is withdrawn from a dosed animal it is not capable of inhibiting further cholinesterase added to it, nor does partly inhibited blood undergo a decrease in activity when incubated *in vitro*.

The inference from this investigation is that parathion administered to a rat is rapidly converted by the liver to an unstable cholinesterase inhibitor. Experiments previously performed in this Laboratory on hepatectomized rats by Dr. M. W. Goldblatt and Mr. J. Frodsham have indicated that the liver cannot be the sole site of such a presumed metabolic change, for when it has been removed a rat is not less sensitive to parathion. Moreover, the miotic effect observed when parathion is instilled into a rabbit's eye suggests that an active cholinesterase inhibitor is produced in the region of that organ. Experiments at present in progress with muscle and other tissues have not so far yielded positive results.

'Double-Action' of Trichothecin and its Production in Soil

TRICHOTHECIN was the name given by Freeman and Morrison[1] to a stable antifungal agent produced by *Trichothecium roseum*. They report the ability of this antibiotic to withstand boiling, and it has been found here that its activity is unaffected by autoclaving for 1 hr. at 20 lb./sq. in. pressure on three successive occasions. This marked thermostability and the neutral reaction of trichothecin have prompted its use in this laboratory for studies on antibiotic production in the soil; *Fusarium oxysporum* var. *cubense* was the test fungus used and the lethal dose 90 was adopted as the activity unit.

A technique was devised for the study of the effect of an antibiotic on mycelial growth as apart from the effect on spore germination and subsequent growth. A standard amount of the test fungus (mycelium on agar) was placed at the centres of a series of plates, each containing 10 ml. of the Freeman and Morrison[1] medium solidified with agar. After incubating for 48 hr. at 25° C., the diameters of the colonies were measured and to the nutrient agar surface was added 5 ml. of the antibiotic solution, each plate being rotated so that the solution formed a liquid film over the surface. The test plates and appropriate controls were then incubated for a further 18 hr. and the diameters remeasured. The interesting result here was that when exceedingly small concentrations of trichothecin (0·00018–0·0018 units/ml.) were used there was a well-marked stimulation of growth. In higher concentrations (0·0018–10 units/ml.) the effect was fungistatic. Above these amounts there was a killing effect, and with 44 units/ml. the effect was wholly fungicidal.

A 'double-action' of long-chain unsaturated fatty acids on some bacteria has been reported[2,3]. When the concentration of trichothecin used was more than 10 units/ml., a pronounced swelling of the hyphal tips was noted, together with a bursting of some of these tips. The surface activity of the antibiotic is indicated by its reducing effect on surface tension.

It is suggested that trichothecin accelerates the bond-break phase of growth. In very minute amounts, trichothecin stimulates growth by slightly accelerating bond-break, enough to allow increased elongation but not enough to result in molecular disorganization. It is thought that it is this disorganization of the molecular make-up of the wall that in higher concentrations is responsible for the inhibition of growth and in still higher concentrations for the swelling and bursting of the tip.

In my experience, there is no report in the literature of a demonstration of the production of an antibiotic in sterile but otherwise untreated soil as well as in artificial media. This point was emphasized more than once at the seventh International Botanical Congress at Stockholm[4]. The following method has provided a positive demonstration of the production in sterile soil of trichothecin by *Trichothecium roseum*.

A sample of sterile garden soil (pH 6) was inoculated with *T. roseum* and incubated at 25° C. for ten days. Shallow layers of this soil-culture were added to a series of Petri dishes and triple autoclaved, together with dishes containing sterile soil as controls. After autoclaving, 10 ml. of Freeman and Morrison agar was poured into each plate in order to anchor the soil layer. An extra 20 ml. was then added to form a smooth-surfaced layer in which the soil was embedded. These plates were left for 20 hr. to allow diffusion into the medium of any antibiotic produced by the growth of the fungus. A standard amount of the test fungus was then placed at the centre of each plate, the plates being incubated at 25° C. for four days. In each case there was a 9·6 per cent reduction in the diameter of the test fungus colony over the soil where *T. roseum* had been grown as compared with growth over sterile soil. After 18 days growth in the soil, a 10·9 per cent reduction in linear growth was recorded.

The Fermentation-inhibiting Properties of Orange Oil

The recent communication by Zukerman[1] leads us to give a preliminary note on our investigations on the antimicrobial properties of orange oil.

The starting point in these investigations was the observation that non-preserved fruit drinks, prepared from emulsified orange oil, inhibited the fermentation at 25° C. at an inoculum of 10^4 cells/ml. *Saccharomyces cerevisiae*[2].

Experiments were carried out with a semi-synthetic medium, containing 10 per cent sucrose and 0·25 per cent yeast autolysate ('Difco') at $pH = 5{\cdot}3 \pm 0{\cdot}2$. Florida orange oil (aldehydes, calculated as decylaldehyde = 1·6 per cent) was added in alcoholic solution to a final concentration of 1 per cent v/v of alcohol. It appeared that 0·01 or more per cent of oil could retard the fermentation of the medium by the inoculum referred to in such a way as increasing the time required for complete fermentation (in blank experiments, 48 hr. or less) to at least 96 hr.

Since Guenther[3] claims that the antimicrobial properties of essential oils such as orange oil are due to the terpenes rather than to the fraction containing oxygen derivatives, a Guinea orange oil (aldehydes = 1·7 per cent) and both the terpenes and the oxygen compounds (3·6 per cent) derived from it by 'Duosol' extraction with 90 per cent methanol/pentane[4] were studied. This investigation revealed that the terpenes possessed the same order of fermentation-inhibiting activity as the oil, whereas the oxygen fraction was inactive in concentrations occurring in additions of orange oil of the order of 0·1 per cent.

During the experiments the terpenes were stored in the refrigerator. They showed $[n]_D^{18} = 1{\cdot}4726$ and a peroxide value of 6·8 m.eq. oxygen/kgm.

Research along these lines is being continued.

I am greatly indebted to Messrs. N.V. Chemische Fabriek "Naarden", Naarden, Netherlands, for their very helpful co-operation in procuring the essential oils and oil fractions used in this investigation.

Chlorosaccus ulvaceus Messik. and Vischer

Between April and October of this year, a rare member of the Xanthophyceæ, *Chlorosaccus*[1], a genus not previously recorded in the British Isles, has been collected on eight different occasions in east Yorkshire. It occurs in two much-shaded streams, one of them near South Cave, the other at Cottingham. From the former locality *Chlorosaccus* has now disappeared and in the latter it is extremely rare.

The pale yellow-green palmelloid colonies become macroscopic, irregular in shape and reach several centimetres in length; they are free-floating or entangled in submerged twigs. Actively swimming zoospores were obtained from material collected in June, July, September and (in smaller numbers) in

October. A full account of the species will be published elsewhere.

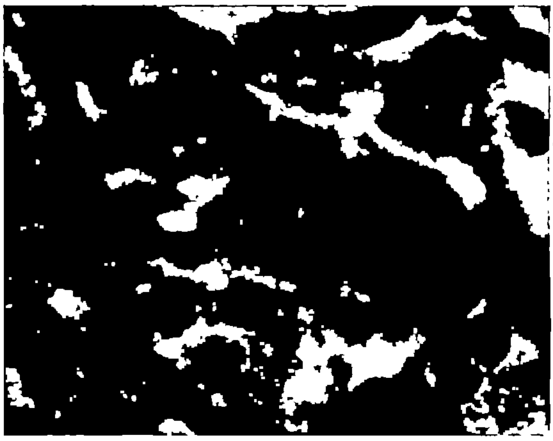
Fluorochromy as an Aid in the Resolution of the Specific Granules of the Islets of Langerhans

Visualization of individual granules in beta-cells of the islets of Langerhans is particularly difficult in many species, including man. Aside from electron microscopy, few techniques provide sufficient resolution to detect variations in the size or shape of individual granules owing to their minute size. Phase microscopy of stained specimens has proved satisfactory for observing extreme deviations from the normal[1]; but variations of less magnitude are difficult to assess. Strongly fluorescent granules illuminated by long ultra-violet rays (λ 300–400 mμ) act as self-luminous sources of visible light located within the specimen, and this permits use of the maximum aperture of apochromatic oil-immersion objectives. As the autofluorescence of islet cell granules is weak[2], their fluorescence must be intensified for adequate results. Various fluorochrome dyes were tried for this purpose and some yielded results which appear definitely superior to those obtained by either conventional or phase microscopy. The methods evolved are briefly outlined here, as most reports concerning fluorescence microscopy of the pancreas[3-4] make little reference to the use of fluorochrome dyes.

Paraffin sections (3 μ) of Bouin-fixed pancreatic tissue obtained from normal Wistar albino rats were washed in tap water until all visible traces of yellow were removed. Thorough washing is necessary in order to remove picric salts, for if these remain in the sections fluorescence is quenched. A number of fluorochrome dyes were tried, including primuline, thioflavine *S*, acridine yellow (*H* 107), acriflavine, coriphosphine, auramine *O* (all obtained from Edward Gurr, Ltd., London) and rhodamine *B* (749, Hopkin and Williams, Ltd., London). Sections were immersed for 2–4 min. in filtrates of saturated aqueous solutions of the various dyes, either alone or in combination. After a brief rinse in tap water, slides were blotted, rapidly dehydrated by a few dips in absolute ethyl alcohol, and cleared in xylol. Preliminary trials with a variety of mounting media indicated that the greater the difference between the refractive index of the granules and that of the mounting media the more intense the fluorescence. Xylol was found very satisfactory for temporary mounts (refractive index 1·494). The light source was a 250-watt high-pressure mercury lamp (British Thomson-Houston) with all appreciable visible light removed by a thick (5 mm.) filter of Wood's glass. A quartz reflecting prism and a quartz condenser were employed, although others of glass will serve almost as well. A Cooke apochromatic oil-immersion objective (N.A. 1·32) was used in combination with a 10 × ocular and a green glass eyepiece filter to eliminate the ultra-violet background. Shillaber's immersion oil was employed because of its low fluorescence.

The best results were obtained with sections stained with acriflavine, although those treated with either primuline or thioflavine *S* were almost equally satisfactory. These imparted an intense (yellowish) fluorescence to the granules in islet cells, as illustrated in the accompanying photomicrograph. After initial treatment with any of these fluorochromes, if the sections are counterstained with rhodamine *B*, the islets are sharply differentiated from surrounding acinar cells, for the latter emit a strong orange fluorescence from their basal portions. Tinctorial differentiation of alpha- and beta-cells was not achieved with any of the fluorescent dyes tried; but characteristics of individual granules are so clearly resolved that cell-types may be identified by the size and number of their granules. In these sections, the granules appear larger than when stained by more conventional methods. Adsorption of dye on the surface of the granule may be responsible, at least in part, for this phenomenon. Alpha-cells appear brighter than beta-cells, for granules in the former are more numerous and closely packed. Beta-cell granules can be so clearly resolved that it is quite possible to observe distinctly their individual size and shape in many instances. This should prove of distinct value in studies of the experimental histology and pathology of the islets of Langerhans.



Pancreas stained with acriflavine illuminated by long ultra-violet rays. Details of fixation and staining are given in text. The unstained nuclei appear as oval black areas. The granules in both acinar and islet cells appear white against a black background. Acinar granules can be seen in the lower right corner. Cytoplasm of an alpha-cell just to the left of this appears almost entirely white, for its granules are crowded closely together. The remainder of the islet, which nearly fills the entire field, is made up of beta-cells. Their granules appear as small white bodies. Final magnification, 1,100 ×

The possibilities of fluorochromy as an aid in visualization of the details of very small structures do not seem to have been fully explored. It is possible that applications of this technique to other organs might be of assistance to cytologists in resolving minute bodies.

The techniques described were developed in the Department of Human Anatomy, University Museum, Oxford, during study leave from the University of Toronto. Thanks are due to Dr. Robert Barer for providing facilities and for his continuous advice and encouragement.

Adaptation in Rodent Moles and Insectivorous Moles, and the Theory of Convergence

STUDIES in connexion with the life-history of the Orange Free State rodent mole, *Cryptomys*, brought to light a remarkable degree of adaptation, anatomically and psychologically, to its mode of life in total darkness.

The most interesting expression of psychological adaptation is observed with regard to the animal's power of orientation, keeping in mind the fact that it is totally blind. Damage to its tunnels may be caused by several factors, the most important of which are large and small Ungulates, rain, dogs and man. The tunnels are bored only a few inches below the surface. In this manner, tunnel damage may be a daily occurrence where cattle and horses are grazing. A tunnel may be damaged to such an extent that, for fairly long distances, it cannot be used. However, where such damage occurs in connexion with mole systems, proper connexion between even widely separated undisturbed tunnel sections is effected in a remarkably short time and correct manner, while at the same time the mole displays highly developed powers of orientation. No matter how severely damaged these tunnels may be, either cutting off the moles in the veldt from the nest or *vice versa*, these animals reach their goal unfailingly without trial or error.

Experiments and observations confirmed this interesting power of orientation, a more detailed discussion of which has already been published[1].

Briefly, the experiments were conducted as follows: (*a*) In one set of experiments a tunnel was opened up for a certain distance, for example, fifty feet from its terminal portion in the veldt; (*b*) in another set of experiments the tunnel was opened up between nest and veldt terminus; (*c*) in still another set of experiments the tunnels radiating from the nest were opened up all around the nest for some distance veldtwards.

In (*a*) the mole plugged the mouth of the undisturbed portion of the tunnel and started to bore another one parallel to the one destroyed, ultimately reaching the veldt terminal spot again. This process of boring parallel to destroyed tunnels has been observed to be repeated as many as twelve times.

In (*b*) the mole, after plugging the one opening, bored another tunnel parallel to the portion opened up, connecting up correctly with the remaining intact portion, the opening of which was then also plugged. As in (*a*), the process may be repeated.

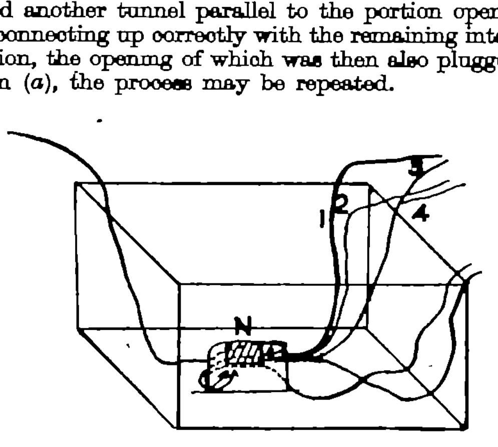

Fig. 1. Tunnels 1, 2, 3, 4 bored consecutively after opening up previous one; thus tunnel 2 is bored after tunnel 1 is opened up. *N*, nest

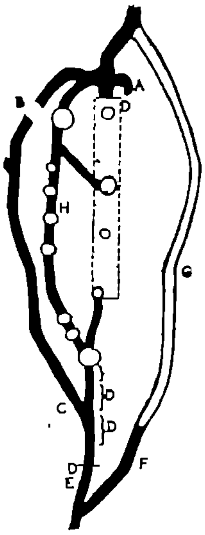

Fig. 2. Orientation in *Bathyergus maritimus*. *A*, Feb. 10, 1951; *H*, tunnel bored Feb. 10; *C*, Feb. 12; *F*, new tunnel bored Feb. 12; *B*, gap of 1½ ft. between two approaching tunnels not completely connected; *D*, tunnel plugged here when opened up on Feb. 13, *E*, tunnel opened up on Feb. 13; *G*, old, plugged-up tunnel repaired and taken into use again

In (*c*) the moles bored nestward, reaching their destination without trial or error (Fig. 1). Here, too, the experiment may be repeated with the same result.

Consequent to these observations on the mole rat *Cryptomys*, observations were also made on three other rodent mole species, including the large dune mole *Bathyergus maritimus*. They all showed the same ability of orientation as *Cryptomys*.

Bathyergus maritimus, for example, is the largest rodent mole of South Africa and inhabits the sandy sea-shores, six hundred or more miles away from the habitat of *Cryptomys*, which inhabits the dry Free State veldt. Its tunnels are dug by means of strongly developed front claws, whereas *Cryptomys* bores by means of its lower incisors, which in contrast to those of *Bathyergus* are separately movable as no ossification takes place at the mandibular symphysis. Thus other differences obtain. However, both species are blind and subterranean. Experiments of type (*b*) described above yielded the same results with regard to *Bathyergus maritimus* (Fig. 2).

Similar observations on the Cape Golden mole, which belongs to the order Insectivora, showed that, so far as orientation is concerned, the two different orders display a high degree of biological convergence, as in fact the absence of visual sense, absence of external ear pinnæ, reduced tail, strong front- and hind-quarter musculature and other anatomical homologies, express the phenomenon of convergence associated with similar mode of living.

An interesting question arises as to which sensory organ or organs make this orientation possible.

Thanks to the fact that the mole rat is easily bred in glass cages containing damp soil, modes of behaviour could be recorded which otherwise might escape observation. By means of apparatus adapted to the mole, we are studying its sense organs, learning ability and reactions. We were greatly struck by the strong and quick reactions (40 σ) to air currents, vibration and sounds. It seems as if the explanation of the orientation behaviour must be looked for in a combination of these senses.

I am grateful to the Council for Scientific and Industrial Research and to Prof. Immelman and Mr. Brits, of the Department of Physics, for technical aid.

A Quantum Mechanical Study of Lithium Hydride

The electronic energy of lithium hydride has been computed by the Hartree–Fock approximation. The computations were carried out both by the linear combination of atomic orbitals approximation according to the molecular orbital method, and by the electron-pair approximation according to Heitler and London with inclusion of ionic terms. When only the two valence electrons were considered, the computed values of the binding energy were as follows:

Linear combination of atomic orbitals approximation of molecular orbitals	3·57 eV.
Electron-pair method without ionic terms	2·64 „
Electron-pair method with ionic terms	3·68 „
Experimental value[1]	2·64 ± 0·2 eV.

In these computations the value of the interatomic distance, R, was put equal to the experimental value, 1·6 A. As the computed energy values are larger than the experimental value, the neglect of the repulsion between the valence electrons and the electrons in the inner shell of the lithium atom seems to cause a considerable error. This fact is in agreement with the result of James's calculations[2] on the lithium molecule (Li_2). Therefore the energy of the lithium hydride molecule was computed with a wave function including molecular orbitals for all the four electrons of the molecule. This more accurate treatment resulted in a computed value of the binding energy of 2·0 eV. when $R = 1·6$ A. The computations will be repeated with other values of this parameter. It seems reasonable to expect that these new computations will result in energy values not much different from the one computed already.

Although the value of the binding energy is evidently rather sensitive to the method of approximation, it may be hoped that the form obtained for the wave function and thus the electron distribution is more insensitive. Both in the two-electron cases and in the four-electron case, the best values of the parameters in the wave function indicate that the structure Li^+H^- is the most important one. This fact emphasizes that no significance should be attributed to the apparently excellent agreement between the experimental value of the binding energy and that computed according to the electron-pair method without ionic terms. The same objection is applicable to the calculations on lithium hydride by Hutchisson and Muskat[3]. The calculated structure Li^+H^- is in good agreement with the experimental fact that hydrogen is obtained at the anode during electrolysis of lithium hydride.

Another interesting point in the results of the calculations is the relative importance of 2*s*- and 2*p*-orbitals around the lithium atom, that is, the degree of '*s*,*p*-hybridization'. If this degree of hybridization is calculated according to the criterion of maximum overlapping, the *s*- and *p*-orbitals are found to be of about equal importance. Almost the same result is obtained when only the two valence electrons are considered in the calculations of the energy. However, when the molecular orbitals of all the four electrons are included in the wave function, the 2*p*-orbital is found to be much less important than the 2*s*-orbital. This result seems to be reasonable, as the 2*p*-energy-level of the free lithium atom lies as much as 1·85 eV. above the ground-level.

Full details of this investigation will be published elsewhere.

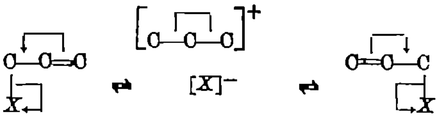
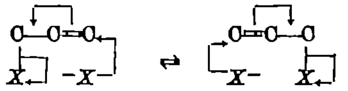
Demonstration of Bimolecular Anionotropic Change

Though it has long been accepted that the unimolecular process S_N1' represents a common mechanism of isomeric rearrangement and of substitution with rearrangement in anionotropic systems, for example,



(S_N1')

the idea has been extant since 1938[1] that a bimolecular mode of rearrangement S_N2' might also exist:

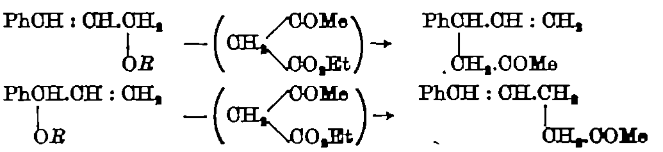


(S_N2')

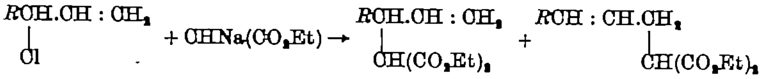
In these formulations X^- represents a general anion, so that the X's which engage in different processes, or together participate in the same process, may, or may not, be chemically identical.

The earlier attempts[2] to detect mechanism S_N2' resulted (*a*) in producing new evidence substantiating the mechanism S_N1', and (*b*) in showing that, under conditions leading only to bimolecular reactions, any bimolecular substitution with rearrangement S_N2' was so relatively unimportant as to be masked by bimolecular substitution without rearrangement S_N2 in the systems studied.

There is, however, one group of cases in which evidence for bimolecular rearrangement S_N2' has been claimed. They are all of one type: the entering substituent comes from a pseudo-acid. By treatment with ethyl acetoacetate and a basic catalyst, cinnamyl alcohol has been converted, probably through its esters, to 1-phenylallylacetone, and 1-phenylallyl alcohol has been similarly converted to cinnamylacetone[3]:

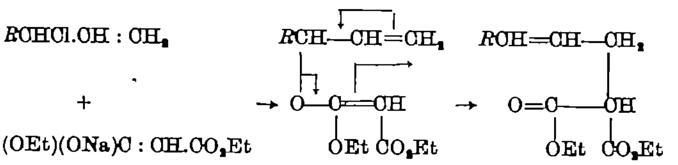


1-Methylallyl chloride has been converted by treatment with ethyl sodiomalonate partly into the normal substitution product, but partly also into the rearranged product, ethyl crotylmalonate; and 1-ethylallyl chloride has been found to undergo similar reactions[4a]:



$$\underset{\text{Cl}}{R\text{CH}}.\text{CH}:\text{CH}_2 + \text{CHNa(CO}_2\text{Et)} \rightarrow \underset{\text{CH(CO}_2\text{Et)}_2}{R\text{CH}}.\text{CH}:\text{CH}_2 + R\text{CH}:\text{CH}.\underset{\text{CH(CO}_2\text{Et)}_2}{\text{CH}_2}$$

However, as Dewar has pointed out[5], the difficulty about accepting such demonstrations of the S_N2' mechanism is that a pseudo-acid always has at least two reactive centres, so that the observed result could arise from a normal S_N2 substitution followed by a Claisen rearrangement (that is, the known intramolecular allyl transformation, as of phenyl allyl ether to *o*-allylphenol):



The formation of rearranged products has also been observed in the reactions of amines with allylic halides; but a careful scrutiny of the changes showed that no unambiguous evidence for the simple S_N2' mechanism could be derived from the results[4b].

As suggested previously, the difficulty about establishing mechanism S_N2' is, not that it does not exist, but that mechanism S_N2 is usually fast enough to mask it. Such masking can be avoided by the following method[6]. The allyl compound, for example, 1-methylallyl bromide, is allowed to interact, under conditions leading only to bimolecular substitution, with a supplied anion, for example, radiobromide ion, identical but for an isotopic distinction with the anion that could be given by the allyl compound. This secures that every individual molecular act of substitution by mechanism S_N2 will, for all ordinary chemical purposes, replace the original molecule by an identical one; so that the original substance never becomes used up by mechanism S_N2, but continues to be available indefinitely for the observation, at any necessary temperature, of isomerization by mechanism S_N2'. The kinetics of the latter reaction can be controlled, and its rate determined, by ordinary chemical means; and this S_N2' rate can be compared with the rate of the S_N2 exchange, which is also kinetically controlled, as determined by radiochemical means. This programme has been carried through for the bimolecular reactions of both 1-methylallyl bromide and crotyl bromide with lithium bromide in acetone. The kinetic data[7] are in the accompanying table: they furnish what at present is the only indubitable demonstration of the S_N2' mechanism.

RATE CONSTANTS AND ARRHENIUS PARAMETERS OF BIMOLECULAR BROMIDE EXCHANGE (S_N2) AND BIMOLECULAR ISOMERIZATION (S_N2') OF ALLYL BROMIDES WITH LITHIUM BROMIDE IN ACETONE
(k_2 and A_2 in sec.$^{-1}$ mole^{-1} l., and E_A in kcal. mole.$^{-1}$)

Bromide	Reaction	$10^6 k_2$ (25°)	$\log_{10} A_2$	E_A
1-Methylallyl	S_N2	879	9·06	16·5
	S_N2'	14·9	9·40	19·4
Crotyl	S_N2	141,000	9·93	14 7
	S_N2'	5	~9	~19

It will be seen that both halides undergo both bimolecular reactions. But for 1-methylallyl bromide, the S_N2 reaction goes 60 times faster than the S_N2' process, while for crotyl bromide the S_N2 exchange proceeds 28,000 times faster than the S_N2' isomerizations. It is easy to understand why the S_N2' mechanism is difficult to observe when a concomitant S_N2 substitution can mask it. However, it is also clear that the difference in the two rate-ratios, S_N2/S_N2', arises mainly from the difference between the two S_N2 rates. Thus it is probable that the great drop in the ratio from 28,000 to 60 is largely a local effect of the 1-methyl substituent in repressing the local S_N2 reaction; and this supports an earlier suggestion[8] that S_N2' rearrangements should be sought in the reactions of 1-*tert*.-butylallyl halides, a task which we now have in hand. The generally reduced rates of the S_N2' as compared with the S_N2 reactions have been ascribed[9] to the circumstance that in the former the reagent attacks a nucleus of unsaturated carbon, which is protected by the double π-electron layer, while in the latter it attacks a nucleus of saturated carbon, which has no such protection. (The π-electrons of C=C will be displaced somewhat towards the group CH_2Br: otherwise the S_N2' reactions would be slower still.)

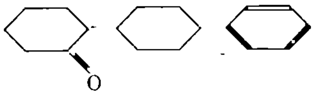
A New Synthesis of *p*-Terphenyl and its Derivatives

WHEN unsaturated ketones in cyclic systems are subjected to Friedel–Crafts reaction[1] in presence of anhydrous aluminium chloride, they give rise to unexpected products. Some significant observations have been made in this laboratory[2] on the Friedel–Crafts reaction involving unsaturated ketones, and this reaction, when extended to *cyclo*hexenyl–*cyclo*hexanone, led to a new method of synthesis of *p*-terphenyl and its derivatives. Although a number of such syntheses have been described in the literature[3–7], the present method offers a more convenient synthesis of *p*-terphenyl and its derivatives starting from easily available materials. Moreover, studies on the condensation of *cyclo*hexenyl–*cyclo*hexanone with biphenyl, *p*-terphenyl, etc., are in progress, which may eventually lead to the development of a new general method for synthesis of polyphenyls.

*Cyclo*hexenyl–*cyclo*hexanone, prepared according to the method of Wallach[8], was condensed with benzene in presence of anhydrous aluminium chloride to give the ketone (I, boiling point 185–190°/2 mm. in 85 per cent yield; semicarbazone, crystallized from ethanol, melting point 227–228°). The ketone I was dehydrogenated by heating with palladized-charcoal (30 per cent) at 260–320° for 8 hr., and the main product isolated after crystallization from benzene–ethanol was found to be *p*-terphenyl (II, melting point 212°; lit.[7] 210–211·5°; lit.[5] 213°; calc. for $C_{18}H_{14}$: C, 93·91; H, 6·08; found: C, 93·74; H, 5·95 per cent). Nitration of *p*-terphenyl, gave the *pp*′-dinitro derivative of *p*-terphenyl (melting point 278–279°; lit.[7] 275°; lit.[12] 277°). Complete separation of *p*-terphenyl left a thick oil which crystallized from ethanol to give *m*-terphenyl (melting point 87–88°; lit.[8] 86–87°; lit.[10] 89°; calc. for $C_{18}H_{14}$: C, 93·91; H, 6·08; found: C, 93·106; H, 5·75 per cent); but attempts to isolate *o*-terphenyl[9] were not successful.



I

II

Reduction of the Friedel–Crafts product by Huang-Minlon's method[11] gave a hydrocarbon (boiling point 170–172°/3 mm.), which on subsequent dehydrogenation by palladized-charcoal (30 per cent) at 260–320° for 8 hr. furnished mainly *p*-terphenyl and a small quantity of *m*-terphenyl; but no *o*-terphenyl could be isolated.

Grignard reaction between methyl-iodide and the ketone I, followed by dehydration of the crude Grignard product with phosphorus pentoxide, gave a liquid hydrocarbon (boiling point 178–180°/3 mm.) which was dehydrogenated by palladized-charcoal (30 per cent) at 260–320° for 8 hr. to give *p*-(2-methyl)-terphenyl (melting point 91–92°, from ethanol; lit.[7,10] 91–92°; calc. for $C_{19}H_{16}$: C, 93·44; H, 6·55; found: C, 93·36; H, 6·46 per cent).

The assignment of the structure I to the Friedel–Crafts reaction product is not above scrutiny, as rearrangement under the drastic condition of dehydrogenation may well have taken place to give *m*- and *p*-substituted products[4]. This finds some support in the isolation from the product of dehydrogenation of a considerable quantity of *m*-terphenyl. However, this point is now receiving consideration.

Microanalyses were carried out by Drs. Weiler and Strauss (Oxford).

Determination of the Mean Life-time of μ-Mesons

THE photographic emulsion method has been applied to the determination of the mean life-time of μ-mesons from their anomalous absorption. Ilford *C* 2 plates with emulsion thicknesses 140 μ, 150 μ and 185 μ were exposed to cosmic radiation under controlled conditions for 42 days during the winter of 1950 in the High Tatra Mountains. One batch of plates was exposed without any absorber at Skalnaté Pleso (1,780 m.) and another one was placed on the top of Lomnický Štít (2,640 m.) under 12 cm. of lead absorber, corresponding in stopping power to the layer of air, 85 gm./cm.², between the two stations. The plates were developed by the freezing method of C. C. Dilworth[1].

The mean life-time τ_0 of μ-mesons was calculated from the formula

$$\tau_0 = \frac{m_0}{p} L, \tag{1}$$

where m_0 is the rest mass of the μ-meson, p is the effective momentum and L is the mean range before decay. The rest mass of mesons was determined by grain counting and Coulomb scattering methods, giving the result $m_0 = 110$ MeV./c^2. The effective momentum p was calculated by numerical integration of the Bethe–Bloch formula and corrected according to B. Rossi and D. B. Hall[2]. The mean range before decay was calculated from the formula:

$$L = -(H_1 - H_2)\left(\log \frac{N_2}{N_1}\right)^{-1}, \tag{2}$$

where H_1 is the height of Lomnický Štít, H_2 is the height of Skalnaté Pleso, N_1 is the number of mesons in a given volume of the emulsion from the higher station under lead, N_2 is the number of mesons in the same volume of the emulsion exposed at the lower station.

Substituting the measured and calculated values of m_0, p, and L in formula (1), we obtained for the mean life-time of the μ-meson, $\tau_0 = (2{\cdot}3 \pm 0{\cdot}3) \times 10^{-6}$ sec., in good agreement with the value $\tau_0 = (2{\cdot}15 \pm 0{\cdot}1) \times 10^{-6}$ sec. from direct measurements.

This method makes it possible to work with mesons in the low-energy region where the absorption anomaly[3] is more pronounced and where the polarization of the medium[3] is negligible. Since it is possible to measure the mass m_0 of mesons from the tracks observed, we were able to determine the value of τ_0 directly, whereas using Geiger–Müller counters it is possible to obtain from the anomalous absorption the value of the ratio τ_0/m_0 only. In this way, our measurements show that ρ-mesons are almost exclusively μ-mesons.

A detailed account of this work will be published in the *Bulletin international de l'Académie tchèque des Sciences*. I am indebted to Prof. V. Petržílka for helpful discussions during the course of this work.

Nuclear Disintegrations caused by Fast Cosmic-Ray Neutrons in Photographic Emulsions

On the same plates as those described in my previous communication[1], I have studied the relation between the single tracks and the stars, and tried to elucidate the question of their origin. A detailed analysis of 600 stars and of 3,000 single tracks was carried out. My measurements support the assumption that the single tracks are caused mainly by fast neutrons in glancing collision with the nuclei of the emulsion. From the topological distribution of the stars on the plates and from the angular and energy distributions of their prongs (protons, α-particles and recoil tracks), I have shown, applying the results of the evaporation theory[2], that the great majority of the stars are also caused by fast neutrons in glancing collision without the capture of the incident neutrons in the nuclei. The energy distribution of fast protons emitted from stars was used to determine the range of nuclear forces following E. Bagge[3] and G. Ortner[4]. From my measurements I obtained the value $\varkappa^{-1} = (2 \cdot 6 \pm 0 \cdot 4) \times 10^{-13}$ cm.

Details of this work will be published in the *Bulletin international de l'Académie tchèque des Sciences*. I wish to express my gratitude to Prof. V. Petržílka for helpful advice in this work.

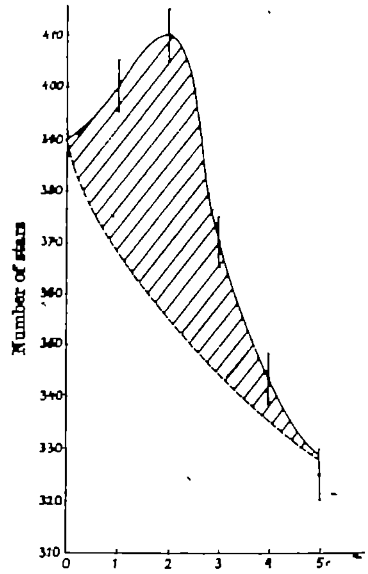
Transition Effect of the Star-producing Radiation

To prove the existence of the transition effect of the star-producing radiation suggested by G. Bernardini[1], an experiment relating to this question was carried out in the High Tatras in the winter of 1950. Six batches of Ilford *C* 2 plates with emulsion thickness of 200 μ were exposed during 45 days at Lomnický Štít (2,640 m.). One batch of plates was exposed without any absorber, while the others were placed under different layers of lead of increasing thicknesses from 1 cm. to 5 cm.

The experimental results concerning the numbers of stars observed in the same volumes of the emulsion under different thicknesses of the absorber are plotted in the accompanying graph. Comparison of the experimental values with the postulated exponential absorption curve shows a well-pronounced maximum of the frequency of stars under the layer of about 20 gm./cm.² lead. The dotted exponential line was drawn using the value for the absorption coefficient $\lambda^b = 310$ gm./cm.².

Further observations are being collected, and definite measurements with possible interpretations of this effect will be published later in the *Bulletin international de l'Académie tchèque des Sciences*.



Transition effect of star-producing radiation : - - - - -, theoretical exponential absorption ; ———, experimental

I wish to thank Dr. J. Pernegr for suggestions and help in this work.

Note added in proof. Since this communication was written, G. Belliboni, L. Fabrichesi, L. de Marco and M. Merlin[2] have published a paper in which they describe measurements similar to those I have made.

The Decay Scheme of Zinc-65

According to a short report given by Good and Peacock[1], the radioactive isotope zinc-65 decays 97·8 per cent by *K*-capture and 2·2 per cent by positron emission. They also found that 54 per cent of the capture processes go directly to the ground-state of the product nucleus copper-65, while 46 per cent go to the 1·11-MeV. excited state.

In the present work, the branching ratio between the two capture processes has been investigated, using a selective method for the detection of the X-rays in addition to X–γ coincidences and a calibrated γ-ray counter.

The source used was a thin layer of finely ground zinc-65 spread on a 'Cellophane' foil and covered with a few drops of a diluted solution of cellulose. This source was placed between two cylindrical Geiger–Muller counters—an ordinary γ-ray counter with 1-mm. thick brass walls, and an X-ray counter with aluminium walls 0·05 mm. thick.

Let K_1 be the number of capture processes going to the ground-state and K_2 the number going to the excited state. Then a branching ratio p can be defined as :

$$p = K_2/(K_1 + K_2). \quad (1)$$

The characteristic X-rays of copper resulting from the K-capture are converted to the extent of about 63 per cent into Auger electrons[2]. As this Auger effect should be of the same magnitude in both branches, p can be written:

$$p = X_2/(X_1 + X_2), \quad (2)$$

where X_1 and X_2 denote the number of X-rays in the two branches.

As the following relation is valid:

$$C = pN_X\,(N_\gamma/N_{\epsilon\gamma}), \quad (3)$$

p can be determined from the absolute microcurie γ-strength of the source $N_{\epsilon\gamma}$, and from the counting-rates of (i) true X–γ coincidences (C), (ii) X-rays detected in the aluminium counter (N_X), and (iii) γ-rays detected in the brass counter (N_γ). Equation (3) holds exactly provided that there is no internal conversion of γ-rays; the conversion factor for zinc-65 is $2 \cdot 3 \times 10^{-4}$ according to Wagooner *et al.*[3], and is thus negligible in this case.

Concerning the quantities in equation (3), C and N_γ can be measured directly with due correction for background and chance coincidences. $N_{\epsilon\gamma}$ was determined from the counting-rates (in the brass counter) obtained respectively from the zinc-65 source and a cobalt-60 standard using identical geometry. However, the value of N_X was difficult to deduce from the measured counting-rate N_{Al} in the thin-walled aluminium counter, because of the simultaneous detection in this counter of positrons and Compton electrons due to γ-quanta.

To avoid these difficulties a selective method was used, based on varying the efficiency of the aluminium counter for X-rays, those for γ- and β-rays remaining constant. The characteristic X-rays of copper (8·05 keV.) are absorbed in the gas only by photo-effect, and this process accounts for the greater part of the counting-rate, the contribution from the walls being relatively small. Therefore the difference of efficiency aimed at is easily achieved by varying the pressure, that is, the absorption probability in the gas, and thus the value of N_X[4]. On the other hand, the yields of γ- and β-rays are scarcely dependent on the gas pressure in the counter, as has been confirmed by special experiments. A somewhat similar method has been described by Gráf[5].

From equation (3) it is clear that, when varying the X-ray efficiency according to the method described, a linear relation between C and N_{Al} is to be expected, since N_{Al} differs from N_X by a nearly constant amount. Thus, the dependence of C on N_{Al} is given by a straight line, and p can be calculated from the slope of this line. Errors in C due to annihilation radiation and scattering are independent of the variation and will thus have no influence on the calculation of p.

The present measurements were carried out at three different pressures of argon, namely, at 90, 270, and 487 mm. of mercury. The results obtained confirm the presumed linearity between C and N_{Al}, and a value of $p = 0 \cdot 44 \pm 0 \cdot 03$ has been found. This is in fair agreement with the value 0·46 given by Good and Peacock.

I wish to express my thanks to Prof. L. Meitner for her help and guidance throughout this work.

Note added in proof (*November* 19). In the meantime, a paper[6] has been published, where zinc-65 is reported to decay to the extent of 0·8 per cent by positron emission.

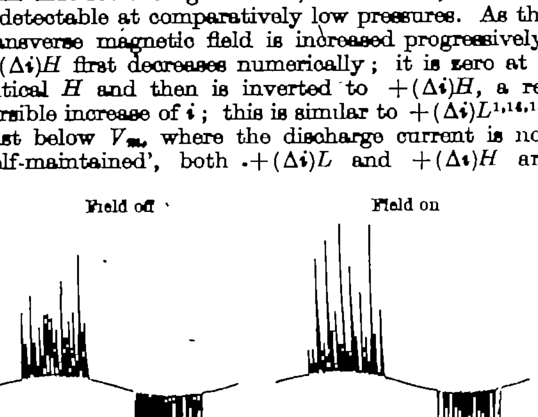
A Magnetic Analogue of the Joshi Effect

FOLLOWING Joshi's observation[1,2] that the discharge current i due to a potential V depends on $V - V_m$, where V_m is the threshold potential characteristic of a discharge reaction, and that V_m is affected by a transverse magnetic field H, we have carried out some detailed investigations of a change with H of i in several gases and vapours excited in an ozonizer, at various frequencies n.

This effect is found ordinarily to be one of suppression $-(\Delta i)H$, which is remarkably similar to the Joshi effect $-(\Delta i)L$ caused by irradiation from the extreme red[3] to X-rays[4]. Both the light and magnetic effects involve practically a negligible time-lag[5,6], are reversible[6,7], are influenced markedly by 'ageing' under discharge[1,8,9], show hysteresis[9,10] which is maximum near V_m and are affected adversely by heating and by increase of n[11,12]. They cannot be detected below the threshold potential[7,13] V_m, where the discharge current i is entirely capacitative ($2\pi nCV$, C being the distributed capacity), despite the use of intense transverse magnetic field H or irradiation. A limited increase of potential above V_m favours either of the negative effects, magnetic field or irradiation being constant. The range of potentials for the production of the magnetic effect is greater than that for the light effect; the former, however, is detectable at comparatively low pressures. As the transverse magnetic field is increased progressively, $-(\Delta i)H$ first decreases numerically; it is zero at a critical H and then is inverted to $+(\Delta i)H$, a reversible increase of i; this is similar to $+(\Delta i)L$[1,14,15]. Just below V_m, where the discharge current is not 'self-maintained', both $+(\Delta i)L$ and $+(\Delta i)H$ are



Exciting potential, 1·8 kV. r.m.s. (50 c/s.); H_2, 0·04 mm. mercury; H, 890 gauss, current change due to H, −29 per cent observed under feeble light[1,12] and magnetic field[16,17] respectively. At a given potential V, either of the transitions[14-17] $-(\Delta i)L,H \rightleftarrows +(\Delta i)L,H$ can be caused *ad libitum* by varying the transverse magnetic field H or the intensity and frequency of light.

Both the light and magnetic effects are linked preferentially with the high-frequency component[5,7,11,12] of the discharge current i. The accompanying pair of oscillograms refers to a discharge in low-pressure hydrogen; essentially similar results are obtained in a number of media with a wide range of operative conditions. On the application of the transverse magnetic field in either half of the current cycle, the amplitude of some of the high-frequency spikes is reduced while that of others increased simultaneously; this is accompanied usually, though not invariably, by a change in the number of high-frequency spikes. A like effect, namely, simultaneous occurrence of $\pm(\Delta i)L$ in different parts of the current cycle, was observed in chlorine[10] and iodine vapour[18].

Our thanks are due to Prof. S. S. Joshi, of Benares, and Prof. V. N. Thatte, of Nagpur, for help and advice.

Formula for Creep Curves of Metals

I WAS somewhat surprised to read in *Nature* of October 20 the letter of Prof. R. R. Hasiguti and his collaborator. Prof. Hasiguti sent me a copy of this letter in April and I replied to him on May 25, by air mail, pointing out that the only reason that he found that the four-constant formula, put forward by him, gave a better fit to his experimental results than my three-constant formula was that he had taken unfavourable values for the constants in my formula. I sent him the correct values of the constants, found by the method of Dr. A. J. Kennedy[1], which are $l_0 = 49 \cdot 57$ cm.; $\beta = 1 \cdot 1006 \times 10^{-2}$ sec.$^{-1/3}$; $\varkappa = 1 \cdot 4713 \times 10^{-4}$ sec.$^{-1}$. With these values, the "Length calculated from Andrade's formula" in Table 1 given in his letter come out to be 50·71, 51 35, 53·16, 57·30, 65·00. Prof. Hasiguti sent me in his original letter a much fuller list of values than that given in his Table 1, and, except at 7 sec., where the experimental reading cannot possibly be accurate (in view of the difficulty of deciding to within a second the moment of imposition of the load, inertia effects and the rapid rate of flow in the first ten seconds), the greatest difference between the values given by my equation and the experimental values was 0·08 per cent as against a greatest difference of 0·10 per cent with his equation. In fact, with the constants given above, my three-constant formula shows a better fit than his four-constant formula.

Unfortunately, the writers of the letter printed in *Nature* do not give the values of their four constants that lead to the figures for s given in their Table 1, and Dr. Kennedy has, after some effort, been unable to find values that yield these figures.

The validity of my formula has been often verified, both inside and outside my Laboratory[2], and it is recognized that the constants β and $\varkappa$ represent definite physical processes, β accounting for slip within the crystal grains of the polycrystalline metal and $\varkappa$ for relative movement of the grains[3]. The constants a, b, c in the four-constant formula appear to have no physical significance.

As far as the single crystal results are concerned, Cottrell and Aytekin[4] found very good agreement between their experimental result on single crystals of zinc and the formula

$$\gamma = \gamma_0 + \beta t^{1/3} + \varkappa t,$$

which is the appropriate form of my formula for a single crystal. As a purely empirical result, Dr. Kennedy has pointed out to me that the experimental results given in Prof. Hasiguti's Table 2 are much better fitted by the two-constant formula $\gamma = \gamma_0 t^{0 \cdot 015}$ than by Prof. Hasiguti's four-constant formula.

"The Home Life of an Astronomer"

I AM very grateful to Prof. F. J. M. Stratton for his appreciative review of my book, "Ninth Astronomer Royal"[1], but I do not understand his saying that I have ascribed Einstein's special theory of relativity to Newton. Unless there is some error that has escaped my notice, this must refer to the statements on page 192: "According to the new Theory of Relativity the rays of light from these stars would be bent in passing the huge mass of the sun. This deflection would be twice as great as anything that could be accounted for by the old Newtonian theory. . . . Would it be the 1·74 seconds of arc indicated by Einstein's theory, or the 0·87 seconds of arc indicated by Newton's, or none at all?" Does this attribute the special theory of relativity to Newton? If so, I err in good company, that of Sir Arthur

Eddington, who writes in "Space, Time and Gravitation": "It must be understood that there were two questions to answer: first, whether light has weight (as suggested by Newton), or is indifferent to gravitation; secondly, if it has weight, is the amount of the deflection in accordance with Einstein's or Newton's laws?" (page 110). Further, "It will be remembered that Einstein's theory predicts a deflection of 1″·74. . . . The simple Newtonian deflection is half this, 0″·87" (page 118).

I gladly admit that I am not competent to do justice to my father's scientific work, but I took the precaution of asking astronomical and other scientific friends to check my manuscript, so I shall be surprised if there are any definite errors of statement on scientific matters in my book. In other respects, the review is only too kind.

MARGARET WILSON

The Chimes,
Radford Rise,
Stafford.

[1] Nature, 168, 440 (1951).

THE use of the words "old Newtonian theory" in connexion with the value of the deflexion of light rays passing close to the sun predicted by Einstein's restricted theory of relativity was the cause of the critical remark of which Mrs. Wilson complains. Newton never developed any theory of the bending of light. He did raise a query whether bodies could bend rays of light. This was one of 22 which he propounded, but left to posterity to follow up. Eddington's reference to the value to be expected for the deflexion according to Newton's laws of gravitation is correct in form; his subsequent statement that "Newton's theory suggests no means for bringing about the bending but contents itself with predicting it on general principles" is misleading and accounts for the reference to "Newton's theory" criticized in my review.

The Clear Representation of Very Small Masses

MANY methods are used for representing small masses; some are not readily legible and others are not immediately comprehensible to those unfamiliar with the notation. Since few editors seem to have a settled policy in this matter, it may be profitable to set out some of the considerations involved.

Two main courses can be followed: we can use one unit of mass, such as the gram, and multiply it by a suitably expressed but complex number; or we can use a series of subunits, such as the milli- and micro-gram, and multiply by a simple number. When the first method was used in the older literature, we often had a long row of 0s. Now we generally have a simple number multiplied by 10 with a negative index, or a neater logarithmic form is used and the whole quantity appears in a negative non-integral index. The latter form has the advantage, shared by the pH notation, etc., that biological response often varies with the logarithm of a quantity rather than with the quantity itself, so that equal numerical intervals in the index correspond to similar changes in response. Each form has the defect that the most important part of the whole quantity, the index, is the least easily legible. With good printing and paper, one can by peering make out the quantity, but many publications now appear 'on grey paper with blunt type' and then the quantity can be lost irrevocably.

A new typographical convention is needed so that any number can be expressed briefly with type of normal size and on the line. The precise convention is a matter of detail which may await decision on the principle, but a strong case can be made for the general use of the prefix p to qualify any unit, as it qualifies hydrogen ion concentration in pH, and indicate that the number following is a negative logarithm.

Most microanalytical needs are satisfied by the subunits milligram and microgram. This sequence has now been[1] extended by the nanogram (ng $= 10^{-9}$ g) and picogram (pg $= 10^{-12}$ g), and it can be logically extended further to the picopicogram (ppg $= 10^{-24}$ g). With such a unit we have reached atomic dimensions, for the carbon atom weighs 2×10^{-23} g or 20 ppg. By judicious use of a subunit, any mass can therefore be expressed by a simple number and there is no need ever to use indices or logarithmic notation at all.

The biologist is sometimes concerned with a small mass; but he is more often concerned with concentrations, so that both mass and volume are being specified. Here simplicity should surely be aimed at and, by the use of units of concentration such as mg or μg per litre, indices and complex numbers should be avoided. In terms of molarity we do not have quite the same flexibility; but even here the more cumbrous forms can be avoided by using mM and μM. Few substances with definable molecular weights exert much action at the latter dilution.

There are obvious advantages in taking one-sixteenth of the mass of an oxygen atom as a unit. Various names and symbols have been proposed for this; for example, h [2], the Cannizzaro unit[3] and the Dalton (d) [4]. With such a unit, molecular masses have the same numerical form as the conventional molecular weight ratios, and there is no advantage in introducing a unit when small molecules are under consideration. But with not readily separable mixtures, for example, the higher fatty acids, the use of a unit increases the precision of a statement without the appearance of too much pedantry. The larger and the less well defined the particle the stronger becomes the case for a mass unit. Thus the application of the unqualified term 'molecular weight' to a protein may lead to a false certainty about what has been demonstrated. This can be avoided by some such phrase as 'particles of median mass 200,000 d or 0·2 Md'.

The points raised here can be summarized in the form of three complementary questions on which I invite comment. Do the advantages of avoiding indices outweigh the difficulties of establishing a new typographical convention? Is pico- a useful prefix, and should editors urge authors to use subunits wherever possible? Is the Dalton (d $= 1/16$ the mass of an oxygen atom $= 1 \cdot 66 \times 10^{-24}$ g) an acceptable and useful unit of mass?

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7.30 p.m.—Discussion on "Glass Plant in Industry and Research" (introduced by Mr. B. H. Turpin).

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. E. N. da C. Andrade, F.R.S.: "The Mechanics of Metal Crystals".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with an honours degree in electrical engineering, and research interests in electronics or radio communications field) in the Department of Engineering—The Secretary, The University, Edinburgh (December 14).

Assistant (Grade A) to teach Engineering Subjects (Mathematics, Drawing and Workshop Technology) to the standard of Inter City and Guilds (Machine Shop Engineering), at Pudsey Technical Institute—The Divisional Education Officer, Education Offices Richardshaw Lane, Pudsey, Leeds (December 15).

Assistant (Grade A) in the Mechanical Engineering Department, South Shields Marine and Technical College—The Director of Education, Town Hall, South Shields (December 15).

Head of the Mathematics Department, Coventry Technical College—The Director of Education, Council House, Coventry (December 15).

Senior Scientific Officer (with an honours degree in biochemistry, and research experience) in the Biochemistry Department, and a Scientific Officer (with an honours degree in chemistry) in the Technical Chemistry Department—The Secretary, Hannah Dairy Research Institute, Kirkhill, Ayr (December 17).

Senior Scientific Officers (4) in the Research and Development Branch at the Electronics Research Laboratory at Adelaide, South Australia, to be responsible to a Principal Scientific Officer for the detailed direction of the work of a team engaged on research and development for new defence equipment in the field of radio, radar and allied techniques—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (December 19).

Hydro-Electric Engineering Consultant for the Thal Development Authority, Punjab Province, Pakistan, under the Commonwealth Technical Co-operation Scheme for South and South-East Asia—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1. quoting D.477/51.OA (December 22).

Physicist (N.H.S. Senior grade), to develop a clinical radioactive isotope service for the hospital, and to carry out research on related biological problems—The Secretary and House Governor, Mount Vernon Hospital and the Radium Institute, Northwood, Middx. (December 22).

Research Director (with high academic qualifications and considerable experience in leading research) for a new large textile research association at Ahmedabad, Bombay State—The Scientific Adviser to the High Commission, India House, Aldwych, London, W.C.2 (December 22).

Senior Lecturer in the Department of Veterinary Pathology—The Secretary of University Court, The University, Glasgow (December 22).

Textile Technologist (with good professional qualifications and research or practical experience in spinning, weaving or wet processing) as Head of the Textile Technology Division of a new large textile research association at Ahmedabad, Bombay State—The Scientific Adviser to the High Commission, India House, Aldwych, London, W.C.2 (December 22).

Assistant Keeper in the Department of Biology—The Director, Museums and Art Gallery, New Walk, Leicester (December 31).

Cytologist (with experience in cancer work; medical qualification not necessary)—The Secretary and House Governor, Mount Vernon Hospital and the Radium Institute, Northwood, Middx. (December 31).

Physical Chemist and an Organic Chemist in the Section of Insecticides and Fungicides at the Long Ashton Research Station—The Registrar and Secretary, The University, Bristol (December 31).

Professor of Economics—The Secretary and Registrar, University College of North Wales, Bangor (December 31).

Assistant Heating Engineer in the County Architect's Department—The County Architect, The Castle, Winchester (January 1).

Bacteriologist at the Institute of Medical and Veterinary Science, South Australia—The Agent-General and Trade Commissioner for South Australia, Marble Arch, London, W.1 (January 2).

Assistant Inspectors of Ancient Monuments (with a University honours degree and enthusiasm for archæology, preferably with some practical experience)—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 4106/52 (January 3).

Engineering Inspector in the Electricity Division of the Ministry of Fuel and Power—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S 4105/52 (January 3).

Assistant Lecturer or Lecturer in the Department of Botany—The Secretary and Registrar, University College of North Wales, Bangor (January 15).

Chair of Physics in the University of Natal, Pietermaritzburg and Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 15).

Lecturer or Assistant Lecturer in Zoology or Botany—The Secretary, Girton College, Cambridge (January 25).

Aerodynamicists for research and development work in the Aerodynamics Department of the Royal Aircraft Establishment, Farnborough, and at a Ministry of Supply research establishment in Bedfordshire. Scientific Officer (Ref. C.722/51A) for aerodynamics research including experimental work in flight, in subsonic and supersonic wind tunnels and general theoretical work; Experimental Officers and Assistant Experimental Officers (Ref. C.723/51A) for experimental work in flight and in subsonic and supersonic wind tunnels, etc.—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

Assistant (Grade B) in the Electrical Engineering Department—The Registrar, Municipal College, Portsmouth

Assistant Lecturer to teach Electrical Installation work leading to the Course B and Course C examinations of the City and Guilds of London Institute, a Lecturer to teach Botany and Zoology to Inter.B.Sc. students and Chemistry and General Science to students of foodstuffs, and a Lecturer to teach Chemistry, Biology and General Science to students of foodstuffs—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

Assistant Meteorologists in Nigeria—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting 27118/5/51.

Civil Engineers (Main grade) (Ref. H.251/51A) and Assistant Civil Engineers (Recruitment grade) (Ref. H.252/51A) in the Air Ministry Directorate General of Works in London and the Provinces—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

Electrical Engineer (corporate member of the I.E.E. with considerable experience in steam power stations and distribution, with knowledge of normal chemical analysis) in the Electrical Services Department, Nyasaland—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting 27326/50.

Electrical Engineers and Physicists (Scientific Officer grade (Ref. A.366/51A) and Experimental Officer grade (Ref. D.523/51A)) at a Ministry of Supply research and development establishment in the South Midlands, for work on Army radar equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

Electrical and Mechanical Engineers (Senior Scientific Officer grade) at a Ministry of Supply Design Establishment in the South-East of London. Electrical Engineer (Ref. D.511/51A) for the design and development of remote power controlled gear and servo systems; Mechanical Engineer (Ref. C.701/51A) for basic development of new projectiles and projectile systems, Electrical Engineer (Ref. D.512/51A) for work on instrumentation for measurement of pressures, stresses, vibration, etc., and for the design of trials apparatus—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

Elizabeth Macadam Research Fellowship for research into the aetiology and pathogenesis of osteoarthritis and/or the aetiology and pathogenesis of spondylitis ankylopoietica—The General Secretary, Empire Rheumatism Council, Tavistock House (N), Tavistock Square, London, W.C.1.

Engineer at a Ministry of Supply establishment, Farnborough, to control a small team dealing with, and be technically responsible for, the development of high-precision components for use in servo systems, and for liaison work within the industry—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting D.517/51A.

Engineer at a Ministry of Supply establishment at Hayes, Middlesex, to control section responsible for the technical direction of inspection of mass-produced miniature electronic devices—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting D.518/51A.

Engineer at the Ministry of Supply Factory at Capenhurst, Chester, to be responsible for the planning, progress and inspection work associated with the operation of a large factory—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs., quoting Ref. 272.

Engineer by the Ministry of Supply in London, to assist in planning and progressing production of electronic fuses and specialized thermionic devices—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting D.516/51A.

Lecturer in the Science Department (duties include the teaching of Chemistry to A.R.I.C. level to part-time day and evening students), St. Helens Municipal Technical College—The Director of Education, Education Office, St. Helens.

Lecturer (Grade B) in Physics—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11.

Mathematicians at a Ministry of Supply research and development establishment in the South-East of London: Senior Experimental Officer or Experimental Officer to take charge of, organize and build up a small computing section; Experimental Officer or Assistant Experimental Officer with interest in applied mathematics or numerical analysis—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting A.254/51A.

Mathematicians and Physicists (Senior Scientific Officer grade) at Ministry of Supply Design Establishments in Kent and Sussex: Mathematician or Mathematical Physicist (Ref. A.360/51A) preferably with knowledge of statistical methods for analysis work in connexion with assessment of weapons performance; Physicist (Ref. A.361/51A) with knowledge of optical and photographic work for scientific direction of Instrumentation Group; Physicist (Ref. A.362/51A) for the determination of rheological characteristics of fuels—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

Organic Chemist with experience in microchemistry (preferably with isotopes) to collaborate in biochemical and biophysical research—The Secretary, Middlesex Hospital Medical School, London, W.1.

Physicists and Physical or Inorganic Chemists at the Ministry of Supply Factory at Capenhurst, Chester, to supervise and participate in the work of a small team engaged in research and development—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting Ref. 268.

Principal Scientific Officer at the Ministry of Supply London headquarters, to assist in the formulation, co-ordination and progressing of the research and development programme in Industry and at Government Establishments in connexion with propulsive units for guided weapons—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting C.706/51A.

Production Chemists for Royal Ordnance Factories in Irvine, Bishopton, Chorley, Swynnerton, Glascoed, Pembrey, Bridgwater, Thorp Arch, London headquarters of the Ministry of Supply, and elsewhere, to assist in technical control or administration of explosives and acids manufacture or ammunition filling, including development work—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting F.542/51A.

Senior Intelligence Officers (with a basis of scientific training, plus wide experience in technical information service and/or training in librarianship) in the Library and Intelligence Division—The Secretary, Research Association of British Rubber Manufacturers, 105 Lansdowne Road, Croydon.

Senior Welding Engineer in the Research and Development Branch, Windscale Works, Sellafield, Cumberland, to conduct investigations into welding techniques of non-ferrous and ferrous materials—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting No. 275.

Zoologist (with at least a second-class honours degree in zoology of U.K. University and, preferably, postgraduate experience) to work at the Zoological Gardens, London, on Fact-Finding Survey of Literature on African Fauna—The Under-Secretary of State (S.610), Research Department, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

THE NATIONAL TRUST

CLOSELY related to the planning of the use of the land in Britain and the inauguration of national parks and nature reserves (see *Nature*, December 8, p. 967) is the work of the National Trust. Both in its recent annual report and at the annual meeting of the Trust on October 12 at which it was presented, the need for action was stressed. Lord Crawford announced that the Trust had just acquired Penrhyn Castle, in Caernarvonshire, with 4,000 acres of agricultural and mountain land. This is three times larger than any other single property which the Trust holds, and the area has been acquired at a critical time. The water-power proposals of the British Electricity Authority cut into the Penrhyn estates both in the Ogwen valley and in the upper valley of the Conway. The transfer to the National Trust means that any electrical development on this land must be approved by Parliament.

The land cannot be acquired compulsorily, even for development, if purchase is opposed by the National Trust, without the Minister's order designating the land as subject to compulsory purchase being first submitted to Parliament. Parliament might, it is true, over-ride the Trust's objection, but that objection would carry great weight, and protection of this character is required in other areas that have been designated for national parks and nature reserves. Transfer of properties to the National Trust does, in fact, increase the safeguard, but this is scarcely the most appropriate general method. If the National Parks Commission and its constituent boards were properly constituted, such procedure should be unnecessary. Appeal to Parliament should only be required after every effort has been made to reconcile departmental claims at a proper level, and one at which there is no suggestion of a department judging its own cause.

What is clear from the annual report of the National Trust, and from its annual meeting, is the extent to which the Trust depends in its work of saving the scenic heritage of Britain on support from individuals. In spite, however, of an increase in membership, the financial position of the Trust is serious. Its membership on June 1, 1951, still stood only at 25,000, with annual subscriptions totalling £18,050. Even if the membership were more than doubled, the position would remain serious, largely owing to the continued work on repairs that accumulated during the war years. The rising cost of such work, together with inflation, is mainly responsible for the deficit of £56,000 on the year. This deficit has been partly met by drawing on the Jubilee Fund, which is now likely to be exhausted by the end of this year, while the repair programme is still unfinished. With a drop in legacies during 1950 to £27,000, as compared with £86,000 in 1949, the anxiety concerning the future of the Trust is understandable.

The Council's report rightly points out that, in an age of extreme taxation and high death duties, it will be more and more difficult for individuals to make gifts to the Trust. The successful pursuit of its work must in future depend increasingly upon the wide support of members and of the general public. Much must also depend upon Government support, both of the authority of the Trust and, particularly if new properties are to be acquired, on some action being taken on the recommendations of Sir Ernest Gowers' Committee on Houses of Outstanding Historic or Architectural Interest. So long ago as April 26 last, the Government of the day stated that it hoped to introduce legislation to give effect to some of these recommendations during the autumn session; but although this is not a party question, it cannot be assumed that the present Government is prepared to accept all the recommendations of the Gowers Committee, or even the same recommendations that its predecessors in office accepted. The possibility that direct relief from taxation will be granted to the harassed owners of historic country houses in return for an undertaking to open them to the public is not yet ruled out, particularly in view of the tacit admission that families should be encouraged to remain, wherever possible, in the houses with which they have been associated, often for generations. The principle that families may be granted some measure of relief by means of grants out of the National Land Fund is unlikely to be repudiated, and it may also be assumed that these grants will be administered by the Ministry of Works, and not by an independent Historic Buildings Council, as recommended by the report.

The Council of the National Trust accepted this decision in view of the assurance that the Ministry would co-operate with local authorities and the Trust, but reaffirms its view that, with its experience and specialized knowledge, the Trust is the body best qualified to hold and administer country houses and estates where the families continue to live but can only do so with assistance. It attaches the greatest importance to the proposal that, where houses no longer remain in the possession of the families, the Treasury should be empowered to accept chattels, as it already has power to accept land and buildings, in part payment of death duties. It is hoped that this relief, which has long been advocated by the Trust, will help to preserve *in situ* the pictures, tapestries, furniture, china and other collections which have been built up in many of the great houses of England and the dispersal of which would be an irreparable loss to the nation.

Here, however, as in regard to the preservation of scenic amenity, the need for action is urgent. "Every year sees the decay or disappearance of more great houses. Those that remain in private ownership are becoming increasingly difficult to maintain. Only some action by the State—whether by relief of taxation or in some other way—can save them. It is not practicable to wait until suitable uses are devised for these houses; action is required immediately and the most important of them should, if necessary, be maintained inexpensively by a skeleton staff until the ideal use can be found. No other course is permissible if our generation is to avoid the last censure of posterity." That statement could apply with equal force to the safeguarding of amenity, in the context of which the Gowers Committee interpreted its terms of reference, and of which the houses were considered to be a part. Particularly where the threats to houses of this character have come from officialdom, the consequences have been generally more disastrous to the setting of the houses than to the houses themselves. The Gowers Committee refers, for example, to Wentworth Woodhouse and Staunton Harold, and like many other bodies deplores both the absence of any effective control over Service and other departments by the Planning Minister, and the practice of allowing, for example, a Minister responsible for producing coal to judge his own cause.

A Conservative Government may well find it easier than a Labour Government to introduce the legislation required to give effect to the recommendations of the Gowers Committee. If such legislation is to be effective, it should be introduced without delay. The present emergency may well make the need more rather than less urgent, though with good will and co-operation between the parties the demands on Parliamentary time might be small. The question of interdepartmental co-ordination remains as pressing as ever. It was ignored during the War; but the reasons that were then accepted can no longer be urged to-day.

Meanwhile, it should be noted that the Council for the Preservation of Rural England, on which has fallen a major share of the responsibility of acting, in countless negotiations and inquiries, as counsel for the defence of natural beauty, is also in financial difficulties. The Council could not expect always to win, nor should it be expected to be infallible in its judgment. But the responsibility of defence can scarcely be left to the Government, because the prime difficulty of the Government in the matter is that it has to judge between such claims and those of government departments. The alertness, energy and persuasiveness with which the Council has brought its great knowledge to bear in defence of natural amenity entitle it to much more widespread and substantial support from the country-lovers it has served so well.

That support must be forthcoming promptly if the Council is to continue its work, and it is to be hoped that one outcome of the work of such institutions as the Council for the Promotion of Field Studies will be to awaken a keener interest in the preservation of the countryside among those young people who use its field-study centres, which will lead them in turn to support the work of such bodies as the Council. Meanwhile, more might be heard of the work of the Nature Conservancy. It is six months since the Conservancy proposed the setting aside of two nature reserves and several sites of special scientific importance within the Lake District National Park. One such reserve has now been created, in Scotland, by the purchase, announced on November 24, through its Scottish Office, by the Nature Conservancy, of 10,450 acres at Kinlochewe, Ross-shire, which will constitute the Beinn Eighe Nature Reserve. A chain of national nature reserves, mostly outside the national parks, was intended as complementary to the national parks. Several of the sites proposed in the Huxley Report have already been endangered by subsequent proposals for training areas, etc. On that score alone it is important to create these nature reserves without undue delay. Once they are established, they can scarcely fail to promote the formation of a public opinion which really understands what is involved, and which will both bring about a new attitude to the use of land and of the national parks and also be prompt to rally to the defence of amenity behind those bodies which, like the National Trust and the Council for the Preservation of Rural England, have done such sterling work in the past.

GRASSLAND: MODERN SCIENCE AND PRACTICE

Grassland and Grassland Products

By Prof. Stephen J. Watson. Pp. vii+200. (London: Edward Arnold and Co., 1951.) 21*s*. net.

IT is fortunate that Prof. S. J. Watson was appointed as Clive Behrens lecturer in the University of Leeds for the sessions 1948–49 and 1949–50, for otherwise it is likely that we should have to have waited some time for this masterly review of what has rapidly become a vast subject and one which goes to the core of modern agricultural practice in Great Britain.

Almost at the outset (p. 13) the reader is left in no uncertainty as to the guiding principle which must lie behind all grassland research and which must dominate practice. This principle is the more tellingly formulated since it is stated in the words of a man—Dr. David Wilson (later Sir David Wilson, Bart.)—who had obtained his evidence as long ago as 1885–88: "compared with the difference of composition at different stages of growth, the differences between the composition of the various grasses cut at the same stage are small". The mass of recent evidence which completely supports this dictum is fully discussed, and the influence of leafiness and rapidity of leaf growth on digestible crude protein is emphasized. It is not so generally realized "that the younger and leafier the plants the greater their content of the major mineral constituents such as calcium, phosphorus and potassium". The trace elements, on the other hand, Watson says, will be related entirely to the soil analysis; it is perhaps, however, premature to imply that a specific influence may not here exert itself. Speaking generally, "the younger the plants the greater will be their value as a source of vitamins".

In the chapters on the growing and management of grassland herbage, the salient points are made abundantly clear. Thus the losses from an acre of good grassland frequently cut for drying "may equal 7 to 8 cwt. of Sulphate of Ammonia, 3 cwt. of Superphosphate and 4 cwt. of Muriate of Potash". Very properly, a considerable amount of space is devoted to permanent grass, and the author does well to quote examples of practices adopted more than fifty years ago with the view of evening out and extending the grazing season—'early bite' is not a new conception. Modern methods of rotational grazings are fully discussed. In so far as ley farming is concerned, a little more might have been said as to the possibilities; and, although beyond the scope of the author's treatment, readers should be reminded that the most important feature of that system is that it adds to the arable acreage and that in a well-balanced rotation the ley sod is an invaluable aid to maintaining the structure and humus content of the soil.

The chapters on the conservation of grass are models of accurate and terse statement. A telling summary of the losses in nutrients that occur in the different conservation processes is given in Table 53. The factors respectively influencing the carotene and protein content of dried grass are fully explained. "The carotene content of dried grass is always falling." It is influenced by the methods adopted on the field, in the dryer and by "time and method of storage". The carotene content "can be no guide to stage of growth or protein content". After a full review, Prof. Watson states that "at the present juncture it is certain that ensilage is the process on which chief emphasis should be laid if we are to utilize grassland to its fullest extent".

The wealth of information packed into these two hundred pages is admirably arranged, the statements of fact are always concise, and at all stages the practical implications are simply and clearly brought out. The book will be of equal value and equally intelligible to the specialist, the student and to the up-to-date farmer. A valuable feature of the book is the excellence of the fifty-three tables, which have the merit of being readily understandable without repeated reference to the text. These are supported by twenty-two well-arranged graphs and diagrams and by thirty-one adequate illustrations. References to the extensive literature quoted are given at the end of each chapter. The index is in keeping with the high standard of the book and very properly is in two parts, author and subject.

R. George Stapledon

THE LOGIC OF ADAPTATION

Analytical Biology

By G. Sommerhoff. Pp. viii+208. (London: Oxford University Press, 1950.) 17*s*. 6*d*. net.

THIS book is a valuable addition to the comparatively small literature which deals with the logical analysis of biological notions. The author is bold enough to tackle the problem of "biological purposiveness", which has often been taken to justify the belief that theoretical biology must operate with categories which cannot be stated in the conventional terms of the physical sciences. He argues that all cases of apparent purposiveness can be regarded as instances of adaptation; and, of the latter concept, he proceeds to offer an attempt at a precise description. His definition is one which can most easily be envisaged in terms of a self-regulating mechanism such as an automatic gunsight.

The basic phenomenon of adaptation is given the name of "directive correlation", and the elements involved in its definition are four in number; the "coenetic variable", which is a prior condition having a causal influence on both the environmental situation which is adapted to, and the response which adapts, these two being jointly affected in such a way that they issue in the goal (or "focal condition") of the adaptation. The logical relations involved in such a notion are discussed both in normal language and in more precise mathematical terms, and the author then proceeds to some applications of the idea of directive correlation to general biological problems. It is, of course, true that such an idea is in no sense an answer to the problems which face biologists; its potential service is to lead to a more precise formulation of them.

Mr. Sommerhoff has made a worth-while contribution towards clarity of thought in a field in which precision has often been sadly lacking, and his book will be of value to all who find themselves tempted to wonder what the conventional biological phrases really denote. It seems to me, however, that he may have over-estimated the applicability of his concept of directive correlation, at least in its simple form. Many instances of "biological purposiveness" seem to involve not so much an adaptation to an external state of affairs, but rather the alteration of the environment to fit in with an internally determined course of action. A bird not only builds a nest to suit the lie of the twigs, but chooses a part of the bush which suits the nest. The model of a crystal growing in an impure solution may be as relevant as that of a radar gunsight. C. H. Waddington

BERKELEY'S SCIENTIFIC WORKS

The Works of George Berkeley, Bishop of Cloyne

Edited by A. A. Luce and T. E. Jessop. (Bibliotheca Britannica Philosophica.) Vol. 4: *De Motu* with an English translation, The Analyst, a Defence of Freethinking in Mathematics, Reasons for not replying to Mr. Walton's *Full Answer*, Arithmetica and Miscellanea Mathematica, Of Infinites, Letters on Vesuvius, on Petrifactions, and on Earthquakes, Description of the Cave of Dunmore. Edited by Dr. A. A. Luce. Pp. viii+264. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1951.) 30*s*. net.

This fourth volume of the new edition of Bishop Berkeley's works collects together those writings which can be labelled as scientific. Of these, "The Analyst" would have been considered the most important in his own day; but "De Motu" has a certain topical interest for the twentieth century which it did not have for the eighteenth.

The Latin text of the second edition of "De Motu" is reproduced here, with a translation by the editor. This essay was written for a prize offered by the Paris Academy of Sciences in 1720, which it failed to win. It would appear to have been hurriedly composed, as the argument is not so well put as in Berkeley's other works, and it does not live up to its very general title. As the editor says, it should have been called "Motion without Matter". Berkeley is arguing that the science of mechanics can be developed in accordance with his own philosophical principles and that by so doing obscurities and inconsistencies, for example, the Newtonian notion of absolute space and motion, can be eliminated. He is expounding what would now be called a Positivist or Phenomenalist interpretation of science, much on the lines of Ernst Mach a century and a half later, to mention only one, perhaps the best, exponent. Of course, Berkeley, unlike later phenomenalists, does not resolve the whole universe into phenomena, but makes a reservation in favour of active minds or spirits.

"The Analyst", first published in 1734, was an important contribution to the long controversy over the use of infinitesimals in mathematics; a controversy of which the echoes still remain and which really began with the paradoxes of Zeno in the fifth century B.C. Berkeley's purpose in entering on the controversy is characteristic of him, and stated in the sub-title, "A Discourse Addressed to an Infidel Mathematician". The mathematician addressed was probably Edmund Halley, who is said to have declared the doctrines of Christianity to be incomprehensible. Berkeley retorted that the doctrines of the new analytical school of mathematics were far less comprehensible, indeed downright contradictory, whether in the form of Leibniz's differential calculus or Newton's fluxions. "It is curious to observe what subtilty and skill this great genius [Newton] employs to struggle with an insuperable difficulty; and through what labyrinths he endeavours to escape the doctrine of infinitesimals; which as it intrudes upon him whether he will or no, so it is admitted and embraced by others without the least repugnance. Leibniz and his followers in their *calculus differentialis* making no manner of scruple, first to suppose, and secondly to reject, quantities infinitely small; . . ." (p. 75). Berkeley concludes that the method works by reason of compensating errors, and "that, however useful it may be, it must be considered only as a presumption, as a knack, an art, rather an artifice, but not a scientific demonstration" (p. 81). This seems to have been Newton's own view when he wrote his "Principia", though Berkeley also attacks some of the statements made there (Book 2, Lemma 2).

The remaining writings in the volume contain Berkeley's replies to critics in the mathematical controversy—good hard hitting, but bringing out no new mathematical points—and some early papers. The one on "Infinites" shows Berkeley already concerned with mathematical problems in 1705–9. The letters on "Vesuvius", "Petrifactions" and "Earthquakes" and the "Description of the Cave of Dunmore" show the strong empirical interests of this idealist philosopher. The editing and printing of this volume maintain the standards of its predecessors; higher praise is not necessary or possible.

A. D. Ritchie

MARINE ANIMALS AND PLANTS

Life of the Shore and Shallow Sea

By Dr. Douglas P. Wilson. Second edition, completely revised and reset. Pp. xvii+213+45 plates. (London: Nicholson and Watson, Ltd., 1951.) 15*s*. net.

The second edition of Dr. D. P. Wilson's popular book on marine animals and plants has been thoroughly revised and reset. The coloured frontispiece has been replaced by a black-and-white study of a John Dory poised over a gorgonid, and though the one hundred and twenty-eight photographs have been reduced to ninety-eight, many of these are new. Pictures are what one looks at first on opening such a book, and no praise can be high enough for the beauty, clarity and artistic merits of Dr. Wilson's photographs of living marine animals. The patience and skill that produced them are unequalled. Feather stars (Fig. 22), the beadlet anemone (Fig. 51), *Physalia* catching a fish (Fig. 61), larvæ from the plankton (Figs. 72–75) and sea horses (Fig. 91) are superb. Each photograph is accompanied by a magnification figure. If a suggestion can be made to so expert a photographer, it is that Fig. 31 of *Asterina gibbosa* does not give a fair idea of this little starfish, owing to the extended position of one of the arms in each of the specimens shown. The publisher and printer are also to be congratulated on the excellent reproduction of the photographs.

The text is as good as the illustrations. As zoologist at the laboratory of the Marine Biological Association of the United Kingdom, Dr. Wilson knows the Plymouth fauna thoroughly, and confines his examples almost entirely to that area. Written in a smoothly flowing style, the book is full of interesting observations on the living animals, their movements, feeding habits, breeding and development, relationships with one another, and the chemical and physical conditions of their environment. Dr. Wilson also draws largely on recent work, such as the studies of Corbin and Steven on the migrations of the mackerel, Moore on the relation between food and shell colour in *Nucella lapillus*, Wells and Newell on the habits and life-history of *Arenicola*, and his own beautiful work on the settlement of polychaete larvæ and the postponement of their metamorphosis until the correct material for their tubes has been found by the larvæ. He refers also to recent work on echo-sounding for the determination of the noises made by marine animals, and to the under-water photography now being undertaken by Dr. H. G. Vevers.

There are two statements that I regret to see perpetuated: the left eye of the young plaice does not 'move' in the sense that the reader will infer from the account on pp. 22 and 163; and the alternation of an asexual and a sexual form (p. 171) is not an "alternation of generations" but of phases in one life-history.

The references to *Chthamalus* on pp. 26, 50 and 68 are to Fig. 41; but this figure shows the wrong habitat for the barnacle. Should the reference be to Fig. 44?

There is an appendix of practical instructions, including useful hints on shore collecting, keeping an aquarium and photographing living marine animals. The book has been improved by its reduction to octavo size. It is very well printed and the price is reasonable.

N. B. Eales

AMERICAN HYDNUMS

The Stipitate Hydnums of the Eastern United States

By Prof. William Chambers Coker and Alma Holland Beers. Pp. viii+211 (60 plates). (Chapel Hill, N.C.: University of North Carolina Press; London: Oxford University Press, 1951.) 40*s*. net.

PROF. W. C. COKER'S important contributions to the systematics of the higher fungi of North America are well known. His publications on the Hydnaceæ (Basidiomycetes) began in 1919, and the present work is a very convenient and welcome summary of the sixty non-resupinate species discovered in the eastern United States. They are placed in ten genera, which follow in the main Banker's classification (1901–13) and which are based on the macroscopic appearance of the fruit-body and the colour and marking of the spores. Twenty-three of these species occur also in Europe, and *Hydnum fragile* Fr. (1852) is given as a synonym of the new monotypic genus *Bankera*. Several of the species occur also in tropical and south-temperate countries. Indeed, in my experience, many of these apparently north-temperate species occur in conspecific or closely related form in the tropics; even the coniferous habitat of many does not seem obligatory, as in the case of *Sarcodon* (*Hydnum*) *imbricatus*, which Coker and Beers report as definitely associated with frondose woods in the eastern United States. Clearly, this book should be on the shelves of all mycologists, or libraries, concerned with the higher Basidiomycetes. The systematics of fungi are cosmopolitan, and this work is one of the indispensable stepping-stones to a world monograph of Hydnoid fungi.

The species are illustrated with characteristically good and well-reproduced photographs, mostly from living specimens, and there are clear line-drawings of spores and other microscopic details, as in Prof. Coker's previous monographs on *Clavaria*, Gasteromycetes and *Boletus*. Spore measurement would also appear precise, though it is not explained how spores, regular or irregular, are measurable to an accuracy of 0·1 μ. The specific descriptions are followed by critical notes on synonymy and related species.

The book bears, nevertheless, too much the stamp of compilation from separate papers, not only in the absence of critical summaries of such interesting matters as seasonal occurrence, geographical distribution, microchemical reaction, and variation in habitat, colour and size, but also in its plan. The usefulness of a systematic work, being primarily one of reference, is greatly enhanced by its usableness. It is not easy to find one's way about this book, small though it be, because the order is not apparent, the generic captions are ill-displayed, and indicative page-headings are lacking. To have always to consult the index does not make a book companionable. I have found that, in the uncertain state of knowledge of the natural affinities of Basidiomycetes, the alphabetical arrangement of genera, species and varieties is the most satisfactory: it is self-explanatory, self-indexing, and without disadvantage when, as in the present case, it is obvious from modern criteria that the genera do not form a natural family and the interrelations of the species, even if rightly placed in the same genus, are dubious. Again, for the comparison of descriptions, it is desirable to conform rigidly to the same order for the parts described and to italicize, as Fries did, the salient features of the species. In the case of the spores (for example, Plates 54–60), they should be orientated with respect to the apiculus, instead of the random presentation in the spore print. Distinctive type is also helpful in the indexing of synonyms along with legitimate names. Incidentally, the expression "threads of the flesh" for hyphæ is surely archaic.

According to the International Rules of Nomenclature, Fries (1821) is the starting point for these fungi. The authors, however, use pre-Friesian names, commonly without reference to the Systema Mycologicum, and in several cases it is impossible to know, without consulting Fries, if the epithet is legitimate, for example, *Bankera fuligineo-alba* (Schmidt) and *Hydnellum zonatum* (Batsch). In my opinion such names are nomenclaturally incorrect because the epithets have no nomenclatural standing, unless as invalid. Thus, to write *Hydnum* L. or *H. repandum* L., as the authors have done, is contrary to the Rules and should be discontinued. A more serious contravention is the absence of any Latin diagnoses for the new genus and two new species described in the book. It is to be hoped that the authors will validate their new taxa in a mycological journal at the earliest opportunity.

E. J. H. Corner

The Oxford Atlas

Edited by Brigadier Sir Clinton Lewis and Colonel J. D. Campbell, with the assistance of D. P. Bickmore and K. F. Cook. Pp. 96+xxvi+90. (London: Oxford University Press, 1951.) 30*s.* net.

A MODERN atlas should show political and natural features, include road communications and aerodrome sites as well as railways and have an index of all names shown on the maps, and, last but not least, should be relatively inexpensive. This "Oxford Atlas" fulfils these requirements. With pages slightly larger than 15 in. by 10 in., it consists of 120 pages of coloured maps (all specially drawn for this publication) and 88 pages of gazetteer entries (more than fifty thousand entries according to the reviewer's reckoning). The first 96 pages of maps cover all parts of the world and are of varying scales, coloured according to layer heights, and the other 24 are distribution maps of weather, population, land use, etc., the colours being used to indicate the relevant statistics.

For those who are more geometrically minded, perhaps the most intriguing part of the Atlas is the discussion of the types of projection used. Two tables give the distribution of errors over conical orthomorphic and transverse Mercator projections, and zenithal projections, respectively. Further, on each map there are figures in the border, those on the right-hand side showing the area in square miles (for that particular latitude) enclosed in the quadrilaterals formed by the parallels of latitude and longitude, and those on the left-hand side showing the distance in miles along each parallel of latitude between two successive meridians.

In the review copy received the detail of some of the maps is somewhat marred by poor workmanship in the colour printing; some obvious misalignments can be seen, for example, where political and natural boundaries should coincide.

Advances in Colloid Science

Vol. 3. Edited by Prof. H. Mark and E. J. W. Verwey. Pp. xi+384. (New York and London: Interscience Publishers, Inc., 1950.) 60*s.*

PROF. H. MARK is an international editor *par excellence*, and by his indefatigable travelling, lecturing, writing and editing in recent years has put all scientific workers in the field of colloid and polymer chemistry in his debt. Dr. E. J. W. Verwey, the other editor, provides an immediate link with the active Dutch school. The result of their editorial collaboration is the third volume of this useful series, which covers a variety of topics in the forefront of interest.

There is an excellent article by J. H. de Boer on atomic forces and adsorption in which he summarizes current theories of attractive and repulsive forces. A. E. Alexander discusses the application of surface chemistry to problems in colloid science and gives a number of interesting examples of which he has first-hand knowledge. G. Overbeek writes on a fundamental subject of which he is a master—the quantitative interpretation of the electrophoretic velocity of colloids. The various factors influencing the derivation of the zeta potential are analysed.

Theories of lyogel structure, old and new, are the topic of E. A. Hauser and D. S. Le Beau. The peculiar properties of thixotropy, rheopexy and dilatancy are described, and hypotheses given to account for their nature. The ultracentrifuge and, in particular, the sedimentation properties of threadlike molecules are the concern of P.-O. Kinell and B. G. Rånby, of the Uppsala school. J. H. Dillon discusses at length the little-understood phenomena of fatigue in high polymers, while S. R. B. Cooke deals with flotation, one of the most recent methods for the concentration of minerals. Altogether, this is a most useful volume destined for a permanent home on the bookshelf.

Ultrasonics

By Dr. P. Vigoureux. Pp. vi+163. (London: Chapman and Hall, Ltd., 1950.) 25*s.* net.

IN the number of books on ultrasonics which have appeared on the market in recent years, this one takes an honoured place. Dr. P. Vigoureux does not, as a number of other writers do, emphasize the technical applications which have been made of this radiation—which, indeed, in many cases are more suited to the industrial laboratory than the production plant—but shows rather what has been done with ultrasonics in the physical laboratory. He begins with an account of the generation and detection of these waves by piezoelectric and magnetostrictive transducers, and briefly describes the methods of observation of the radiation in fluids. Then follows an account of velocity data and—more briefly—absorption data in gases and liquids, and the theories which have been put forward to explain them. This is as far as the survey goes and, in particular, propagation in solids is not discussed.

A comprehensive bibliography of some three hundred papers dealing with these topics since 1939 is included; but the author has not always been careful in consulting his references, as occasionally measurements are ascribed to the writer of a general article or to the *rapporteur* of a symposium rather than to the man of science who did the work so reported. This is, however, a small point and does not detract from the merit of this useful survey.

E. G. R.

Metallurgical Abstracts (General and Non-Ferrous)

Editor: Lieut.-Colonel S. C. Guillan; Assistant Editor, Major W. G. Askew. Vol. 16, 1948–49. Pp. viii+1048. (London: Institute of Metals, 1949.) 60*s.*

THIS volume fully maintains the high standard of scientific writing associated with "Metallurgical Abstracts", a publication which is a necessity for any scientific worker concerned with non-ferrous metallurgy. The abstracts are well and clearly written and give as much detail and numerical data as can be expected. The defect of the work lies in the uncertainty existing as to how much ferrous metallurgy is included. On the purely scientific side, ferrous and non-ferrous metallurgy are part of one subject, and the present system means that many scientific workers have to consult both the Metallurgical Abstracts of the Institute of Metals and those of the *Journal of the Iron and Steel Institute* if they are to keep in touch with their subject. Seeing that both Institutes occupy the same building, this production of independent abstracts with uncertain overlapping is scarcely to their credit; and if a joint publication cannot be produced, metallurgists may reasonably ask for a common index. On the publication side, the present volume is not well bound. One omission noted is that of a list of the journals abstracted.

W. HUME-ROTHERY

ROYAL SOCIETY

ANNIVERSARY ADDRESS BY PROF. E. D. ADRIAN, O.M., F.R.S.

AWARD OF MEDALS, 1951

Copley Medal

THE COPLEY MEDAL is awarded to Prof. D. Keilin for his fundamental researches in the fields of protozoology, entomology and the biochemistry of enzymes.

Prof. Keilin's early work was on parasitic insects, and it contains much that is of lasting value and some which is regarded as classic. He made brilliant studies on the Anthomyid larvæ, on viviparous reproduction in higher flies, and on intersexes in the human louse.

It was Keilin's interest in parasitic insects which led him to study the peculiar hæmoglobin in the larvæ of the horse bot *Gastrophilus*, and from this developed the brilliant series of biochemical investigations which, in the ensuing twenty-five years, have resulted in his numerous important discoveries concerning hæm compounds and a range of catalysts of biological oxidations.

In 1925 Keilin published in the *Proceedings of the Royal Society* a paper "On Cytochrome, a Respiratory Pigment common to Animals, Yeast, and Higher Plants"; here he advanced evidence that the cytochrome system, consisting of three different hæmochromogen compounds, functions as an oxidation system in aerobic respiration. The general scheme developed in this paper for the aerobic respiration of cells has proved to be of fundamental importance, and Keilin's own contributions to this field have been remarkable in their variety and significance. Many of these have dealt with hæm, hæmoglobin, and their derivatives; in addition to characterizing components of the cytochrome system, he purified catalase and peroxidase and proved that these well-known enzymes are hæm compounds. He has studied the mechanism of the catalytic action of the different hæm compounds and demonstrated the part they play in cellular processes. In particular, he showed that the previously known indophenol oxidase in animal tissues is the specific oxidase for cytochrome *c*; he established the part played by the cytochrome system in the aerobic oxidation of succinate in tissue preparations; and his studies have thrown light on the mode of action of various respiratory inhibitors.

Keilin purified polyphenol oxidase and laccase, and showed that these enzymes are copper proteins. He discovered also hæmo-cuprein and hepato-cuprein, copper proteins from red blood cells and from liver respectively. The purification of carbonic anhydrase led to its characterization as a zinc protein. His researches have thus illuminated the role of other trace elements in addition to iron.

In these researches, and in others too numerous to mention, the work of Keilin displays constantly his powers of acute observation and brilliant analysis; and while he is able to focus these powers sharply upon the crucial detail of a biochemical problem, his deep interest in the wider biological setting is at all times evident.

Royal Medals

A ROYAL MEDAL is awarded to Sir Ian Heilbron for his distinguished contributions to organic chemistry, particularly in the field of vitamin A and polyene synthesis.

Sir Ian is distinguished for his many notable contributions to organic chemistry, particularly in the field of natural products and in the development and exploitation of synthetic methods applicable to them.

After some early researches on various dyestuffs, Heilbron made his first really important contribution by his work on the triterpenoid hydrocarbon squalene, which occurs in fish oils, and by his structural elucidation of batyl and selachyl alcohols from the same sources. This marked the start of a great research programme on naturally occurring unsaturated aliphatic compounds which has continued to the present time. His work on squalene was followed by research on the carotenoids and vitamin A, and in this he made extensive use of physical methods of investigation. His synthetic work in the carotenoid–vitamin A field led to the development by him of acetylene chemistry, and the numerous reactions of acetylenic compounds discovered by him have been applied in many fields. Of particular interest is the re-arrangement of acetylenic carbinols derived from unsaturated carbonyl compounds, which has permitted the synthesis of long conjugated polyene chains and made possible the total synthesis of β-carotene by other workers.

In the chemistry of steroids Heilbron has carried out pioneer work on ergosterol, on the irradiation products of ergosterol and on algal and fungal sterols. His extended researches on the triterpenoids included the discovery of the key alcohol, basseol, which has played a vital part in the systematization of the group. During the Second World War he made notable contributions to the chemistry of penicillin, and it is typical of him that he has exploited to the full novel synthetic reactions discovered in the course of his work on this subject and showed that they had wide application in other fields. His novel and elegant methods for the synthesis of purines, amino-acids and peptides are based largely on thiazole intermediates and stem directly from his penicillin work.

From the earliest days of his career Heilbron has realized the importance of the relationship between the physical properties of a compound and its molecular structure, and he has been a pioneer in the application of absorption spectroscopy and chromatography to organic chemical investigations. British chemists are probably more indebted to him than to any other chemist for the introduction of these techniques, and his influence has spread far beyond the confines of his own laboratory.

A ROYAL MEDAL is awarded to Sir Howard Florey for his distinguished contributions to pathology by his studies of the functions of mucin and by his work on penicillin and other antibiotics.

Sir Howard Florey is most widely known on account of his work on penicillin during the Second World War, and it is due chiefly to his initiative, and his persistent attack on the many difficult problems involved, that penicillin now holds the place it does in modern therapy.

Quite apart, however, from this outstanding contribution to medicine, Florey has established a reputation as one of the leading exponents of the experimental method applied to problems of physiology and pathology. He devised new techniques for the study of acute inflammation in the living animal, and by the use of cinematography demonstrated the part played by various types of cells in this process and also clarified the vexed question of the origin of the mononuclear phagocytes. He has made important contributions to the physiology of the small blood vessels of the brain and its membranes, emphasizing their control by the nervous system. He demonstrated the rhythmical contractility of some of the lymphatics in mammals, and by a study of lymphatic function showed the part played by these vessels in the removal of fluid from tissues.

Florey made the first detailed investigations into the production and function of mucus in different parts of both the respiratory and gastro-intestinal tracts and in other mucous membranes of mammals, including trachea, stomach, intestine and especially the colon. He thus established the part which mucus plays in removing irritants and other foreign material from the mucous membranes. Similarly, he was one of the first investigators to supply precise and accurate knowledge of the relationship of Brunner's glands to duodenal secretion, and he afforded the first definite proof that these glands are under nervous control.

His studies on regeneration of tissues and organs made significant additions to our knowledge of regeneration in the alimentary canal, and the remarkable powers of regeneration of lymph nodes even when mere fragments of such nodes are available for stimulation.

His impressive contributions to scientific knowledge in various fields of both physiology and pathology, and the part he has played in the practical applications of both his own work and that of others on antibiotics to the relief of human suffering, make Sir Howard Florey eminently suited to be the recipient of a Royal Medal.

Davy Medal

The Davy Medal is awarded to Sir Eric Rideal for his distinguished contributions to the subject of surface chemistry.

Sir Eric's work has covered a very wide field in physical chemistry; but the major theme has been surface chemistry and chemistry of colloids. He may be said to be the leader of the science of surface chemistry in Great Britain, and has done much to transform what was once a rather vague and unsatisfactory subject into one with a modern scientific form.

One of the principal fields of his activity has been the study of what may be called the two-dimensional state of matter. He and his collaborators have done much to apply special techniques for investigating surface films, including, for example, that which depends upon the measurement of the difference of potential at the surface. This has allowed many conclusions to be drawn about the structure and configuration of surface films and about the reactions which occur in them. This work has been extended to systems of biological importance, but it is only one of many examples of studies in which new and stimulating contributions have been made.

Another field is that of catalytic reactions, for example, hydrogenation at metal catalysts, in which the role taken by hydrogen atoms and other reacting species has been examined by *ortho-para*-hydrogen conversion and other techniques. Rideal has played a prominent part in the development of every possible physical method for the purpose, and in this respect has often launched junior collaborators on lines which they have continued to prosecute fruitfully to other ends. His influence on a large School has been profound and lasting, and he has done much for the healthy development of physical chemistry in Great Britain over the past twenty-five years.

Hughes Medal

The Hughes Medal is awarded to Prof. H. A. Kramers, professor of theoretical physics in the University of Leyden, for his distinguished work on the quantum theory, particularly its application to the optical and magnetic properties of matter.

Prof. Kramers' work covers a wide variety of fields, but his name is best known in connexion with the early application of quantum mechanics to atomic structure and radiation. In this field he has given constant inspiration to his students, and the spectacular development of quantum electro-dynamics in the past five years owes not a little to his influence.

His work in statistical mechanics also holds a high place, particularly his exact solution (with Wannier) of a problem in co-operative phenomena, which was the first success in a difficult field, yielding important results on which much subsequent work has been based. His work on magnetism and the lowest quantum states of atoms and ions, particularly the phenomena of Kramers degeneracy, is equally well known. The group theoretical methods developed for this purpose he later applied to the theory of the positron, introducing the now familiar concept of charge conjugation into the quantum theory of the electron field. In fact, it may be said that Prof. Kramers is one of the foremost theoretical physicists of the present time.

I must not conclude my year of office in the presidential chair without thanking my brother officers and Council for making it so easy. It is true that the year has not produced any major convulsions, any great expansion or alteration in the work which the Society undertakes: we have resisted the urge to set up new committees and have allowed one or two to hibernate; but we seem to have made the usual number of decisions and our business is not in arrears. If Council has had few lengthy meetings and no quarrels, it is not because we have had no important questions to settle; but because our business has been so well presented to us by Dr. D. C. Martin and his staff. Thanks to them we do not have to waste our time talking at cross-purposes. Thanks also to Sir Edward Salisbury and Sir David Brunt, our scientific meetings have maintained a high standard, both in regard to the matter presented and the clear manner of its presentation, and to the numbers attending. The policy of inviting the directors of various research institutes to give us an account of what they are doing has produced meetings of great interest, and the Fellows have had the privilege of visiting some of the laboratories to become acquainted with their work at first hand.

Although science does not advance because someone has set up a new committee, it is never a waste of time for scientific men to leave their laboratories to see new work in progress and to meet the men who are engaged on it; it is so much the better if the work lies outside the narrow field which they cultivate themselves. At the present time those of us who have much to do with the business of the Society feel this need particularly. The Royal Society has an important duty to the State, for it is an independent self-elected body; and because of this closely guarded independence it can act as an impartial adviser to the Government on matters of scientific policy; and the modern State has so many scientific activities and so much may turn on their wise direction that our responsibility is not to be treated lightly. If we are to give good advice, it is important that as many of us as possible should be well informed on the whole scientific effort of the country. Much of that effort is now expended in research institutes not directly attached to universities and in work which is not published in the journals devoted to academic science, since its purpose lies in the application of science to industry or agriculture or to the health of the community. We cannot afford to be ignorant of such work, and we have welcomed the opportunity of learning of it at first hand: we are most grateful to the directors and staffs of the institutions who have instructed us and to our secretaries who have induced them to do so.

The increasing difficulties of scientific publication are a source of anxiety to all scientific bodies. On the Secretaries of the Society falls the considerable burden of editing our *Proceedings*: the A *Proceedings* are now published at the rate of 3,000 pages a year, and the interval between the receipt of a paper and its publication has been reduced to an average of thirty weeks. But constant encouragement of referees and a constant effort at every stage is needed to prevent delay, and it may become necessary to take fresh steps to lighten the secretarial burden.

There is sad news about one of our publications. Dr. de Beer's many duties have made it impossible for him to continue the editorship of the *Notes and Records* of the Royal Society. In his hands this has become not merely a record of our ceremonial doings during the year but also a journal to which we can all turn to be reminded of our long history. Many of the papers which Dr. de Beer has published are important contributions to the history of science, and in every number there has been some interesting sidelight on the early days of the Society and on the work and fortunes of our great men. We are exceedingly sorry to lose the editor who has done so much to create this attractive addition to our more austere publications.

In his anniversary address last year, Sir Robert Robinson announced the appeal to create the Rutherford Memorial Fund, and the appeal was launched simultaneously in other parts of the Commonwealth. It was hoped that a sum of at least £100,000 would be raised, and I am glad to announce that in the United Kingdom about £70,000 has already been given or promised. In Canada the fund has reached 40,000 dollars and the National Research Council has offered one of its post-doctorate fellowships as the Canadian Rutherford Research Fellowship. We have news that Australia, India, South Africa and New Zealand, the birthplace of Rutherford, are collecting funds; our own lists are not closed, and we can be confidently assured that the £100,000 asked for will be exceeded. Encouraged by the response to the appeal, the Rutherford Memorial Committee has taken steps to advertise the first of the Rutherford scholarships, and the first Rutherford Memorial Scholar will be appointed to take up his scientific work in some part of the Commonwealth on October 1, 1952. Dr. E. Marsden has collected together the correspondence of Rutherford, and copies of this will be placed in those universities with which he was associated, namely, Canterbury College in New Zealand, McGill University in Canada, and the Universities of Manchester and Cambridge. On the recommendation of the Committee, Council has appointed Sir John Cockcroft as the first Rutherford Memorial Lecturer, and it is proposed that he should visit New Zealand in the autumn of 1952. By a happy concurrence of events he will go as a Nobel laureate for the work which he did in the Cavendish Laboratory under Rutherford. In fact, this year's award of the prize for physics to Cockcroft and Walton could not have been better timed as a reminder of all the great discoveries which had the stamp of Rutherford's genius on them.

There is one other honour which has given us all great pleasure. In the King's Birthday Honours List this year our accountant, Miss Roberts, was awarded the M.B.E., and all those who are familiar with the intricate business of the Society will know how well such recognition was deserved, and we can all join in congratulating her.

Dr. D. C. Martin, assistant secretary of the Society, has just returned from a five weeks visit to Canadian scientific institutions and universities at the invitation of the National Research Council of Canada. There and in the United States he has been able to see something of the organization of the academies and research councils whose members we know so well but whose collective responsibilities differ in some way from ours. The personal contacts which Dr. Martin has made will make it far easier for us to have a clear picture of the direction of scientific research on both sides of the Atlantic. There was no need to establish friendly relations with our colleagues; but it will help our mutual interests if we know something about what may be called their extra-laboratorial activities.

The need for personal contacts with the scientific men of our Commonwealth cannot be stressed too much. It is true that distances are short nowadays and that we are bound together by other ties than that of a relatively soft currency; but we are the oldest member of the family and the Royal Society has special obligations to fulfil. Our Fellows, elected for their science alone, have always been drawn from the whole Commonwealth. At present we have eighteen Fellows in Canada, twelve in Australia, seven in India, four in South Africa, three in New Zealand and two in East Africa. The number has risen in recent years and it must rise still further to keep pace with the increasing scientific effort overseas. I was privileged to witness some of this effort on a recent visit to Australia to attend the jubilee meeting of the Australian and New Zealand Association for the Advancement of Science, and on my return journey, which included a brief visit to the Royal Society of Canada. I hope the time may come when longer visits can be paid as a matter of course, when economic conditions may allow junior as well as senior men of science to move freely within the Commonwealth, to stay in any centre where important work goes on.

During the year the Society has been enabled by bequests, particularly by the Locke and the Stothert bequests, to increase its effort in the medical field by appointing three new research fellows. We have appointed Dr. C. E. Lumsden as Henry Head Research Fellow; but at the end of the year we shall be very sorry to lose our Foulerton Professor. Prof. A. V. Hill retires after a tenure of twenty-five years, during which he has given whole-hearted service to the Royal Society not only by scientific work of the highest quality, but also by his unselfish abandoning of that work when his help was needed in a wider field. That he could return to his laboratory to such good purpose after the War was no surprise to those who knew him, and we are very glad to think that his work will not be interrupted by his retirement from his chair.

I have kept to the last an item of our news which has given the greatest pleasure to all of us. On May 3 the Royal Society honoured itself by electing H.R.H. the Duke of Edinburgh as a Fellow under Statute 12. His visit to Burlington House to sign the Charter Book was a delightful occasion, and all those who listened to the Duke's presidential address to the British Association in Edinburgh will realize our good fortune in having such a worthy, as well as such a distinguished, addition to our roll of Fellows.

PHYSIOLOGY OF THE NERVOUS SYSTEM

Natural science advances so rapidly that it would be pointless to try to survey the front line or to predict where the new movements will be. At the moment the most striking activities are still those which have come from the peaceful application of war-time research, for we are still reaping the fruits of highly organized scientific effort directed into unusual channels and maintained at fierce intensity for the six years of the War. Medical research still feels the impetus of penicillin, developed to combat septic wounds, and medical scientists have still to sample all the possibilities of an abundant supply of isotopes and radioactive materials. Their use as tracers in the body has already passed into clinical practice as well as into the practice of engineering and of the chemical laboratory. Physical science enjoys the technique of radar and short-wave communication, developed to thwart the approaching enemy and now used for investigating the upper atmosphere and the farthest extensions of space. It has given us the new science of radio-astronomy with its detailed maps of invisible material in the region of the fixed stars, and we are still wondering what these maps reveal. The electronic calculating machines have multiplied and are kept busy solving problems in pure mathematics instead of in ballistics, and those who use them are not afraid to compare their powers with those of the human brain.

In the face of such advances physiology has little to show, although the radioactive tracer method has given some striking confirmation of biophysical theories. But the physiology of the nervous system still offers an enticing variety of problems which lead beyond the specialized regions of pure neurology. They do so because we suppose that a better understanding of the nervous system will lead to a better understanding of its most remarkable product, the behaviour of the human species.

The prospect is not free from all anxiety. A better understanding of the roots of human behaviour will almost certainly lead to an increased power of control: this in itself is not a responsibility to treat lightly, and at present we are in the difficult stage of having some control but little understanding of its nature. It is known that behaviour can be changed by certain operations on the brain and that the effects of the change can be beneficial to the subject, but we do not know why they occur. The study of such effects falls mainly to the psychiatrist, for the most that can be done by a frontal leucotomy or lobectomy is to reduce the excessive cares which have interfered with normal life. But without more knowledge of why the change comes about, we are a long way from any precise control of the forces which lead to anxiety and self-criticism. What is remarkable is not so much that they can be altered by interfering with the structure of the brain, but that these particular forces can be dissected out, so to speak, leaving the rest of the personality not greatly altered. We do not know enough to predict how far such dissection might go, but it has to be realized that the surgery of the brain is much less formidable than it used to be. All kinds of interference can be done with impunity, and electrical records of the brain's activity are now used before and during the operation to guide the surgeon to a diseased focus.

This line of approach is still largely empirical. An entirely different line is that which uses the theories of the communication engineer and the analogy of the calculation machine to define the functions and powers of the nervous system and to suggest the way in which these functions may be carried out. The brain has been so often compared to a telephone exchange that it is interesting to have this new and much more informative comparison with the mechanism of electric controlling devices. It stresses the feed-back system which is used to control movement by the aid of signals sent back from the moving parts to the controlling mechanism. The nervous system certainly achieves its nice control of the muscles by the aid of such a feed-back. This was shown by Sir Charles Sherrington in 1893, and it is a measure of the importance of the system that, of the nerve fibres supplying the muscles, Sherrington found as many as a quarter to a half to be sensory and not motor in function. Quite recently the system has turned out to be even more elaborate than we used to think. Kuffler has found that, of the efferent nerve fibres in the motor roots of the spinal cord, only two-thirds are concerned in producing muscular contraction: the remaining third, distinguished by their smaller diameter, go to the receptor apparatus, the muscle spindles which are sensory elements in the feed-back system, and alter their sensitivity according to the circumstances of the movement. We can say, therefore, that more than half the nerve supply of a muscle is concerned in the central adjustment of the motor nerve cell discharge.

The small nerve fibres which adjust the sensitivity of the muscle spindles are clearly an important part in the feed-back system, but most of the sense organs have some adjusting mechanism to focus them on their source of information, to move them so as to scan it and to protect them from too intense excitation. Thus the nerve fibres to the muscle spindles are comparable to the nerve fibres which open and close the pupil of the eye to admit more or less light. At all events, although we have been well aware of the way in which all movement, visceral as well as skeletal, is regulated by signals from the moving parts, it has been of great value to physiologists to have their problems examined from an entirely different angle and brought into line with similar problems in man-made mechanism. For, those who study the nervous system are always faced with the dilemma arising from its structure: it is made up of a very large number of cells all of which behave, we suppose, according to much the same general principles, but the co-operation of these cells achieves the unified and purposive behaviour of the individual. We can begin at either end, studying the cell reactions, the impulses in the nerve fibres and the synaptic events to see how these might be built up into an integrated system, or we can try to analyse the final product into simple components, as Sherrington did in his study of the spinal reflexes. After a period in which the single units have been in the foreground, we are coming to realize how much depends on their co-operative effect, particularly on the sensory side.

The importance of the feed-back mechanism is one reminder of this; but we have others from the action of almost any of the sense organs in the body. To illustrate this I am going to consider a sense organ which has suffered undue neglect, largely because it plays a relatively small part in guiding human behaviour. Sensations of smell are chiefly interesting for their great variety. The olfactory organ is very large, with a sensory surface which in many animals is much greater than that of the eye; and clearly there must be some differences in its reaction to all the different kinds of molecule which have a distinctive smell. It is not difficult to record the impulses which are sent from it into the brain when it is stimulated by smell; they are of the familiar kind, with the frequency increasing with intensity of excitation, and from a study of these impulse discharges we might hope to find out how olfactory discrimination is accomplished. It is too early to give a definite decision, but it looks very much as though discrimination depends in the main on differences in the general distribution of excitation over the whole organ, in the spatial and temporal pattern of the activity set up by the arrival of different kinds of molecule. There are slight but distinct differences in the sensitivity of different receptors to different kinds of smell, for when we use threshold concentrations we often find that the impulses are set up in different conducting units; there is no rigid differentiation of the receptors, however, for most of them react to most smells when their concentration is much above the threshold. But the receptors with these slightly different properties are not evenly distributed over the whole organ, and so it comes about that particular smells in weak concentrations have their greatest effect in particular regions. This regional effect turns mainly on the solubility of the stimulating substance in the watery layer which covers the olfactory membrane: at all events, substances which are soluble to some extent in water have a greater effect in the anterior parts of the organ, and those which are soluble only in oil have a greater effect in the posterior parts. There is a similar distinction in the speed of the reaction, for the latency of the discharge is considerably shorter with water-soluble than with oil-soluble molecules.

Clearly there must be other factors involved, chemical as well as physical, if the organ is to give a distinctive pattern of excitation for every kind of smell; but its surface is large and there will always be outlying regions which are reached by only a few of the molecules, so that slight differences in sensitivity may well show up in the distribution and timing of the discharge from different parts of it.

Studies of the olfactory organ place the emphasis more on the whole pattern of the discharge from it than on the reactions of the individual receptors, though these certainly determine the pattern. But the emphasis ought really to be shifted still further. The olfactory organ is not the only sensitive structure in the nose. The whole of the surface of the elaborate turbinate bones in front is supplied by sensory fibres from the fifth nerve, and many of the substances which we can smell excite these sensory endings as well as those in the olfactory organ. The action of ammonia is a good example. If we sniff a solution in water we are usually aware that the sensation has some localization to the front of the nose. A rabbit turns its head away, as we do; but when we examine the discharge from the olfactory organ in the rabbit, we find that it is small or absent altogether. The fact is that in the rabbit, where the anterior turbinate bones are much more elaborate than ours, the ammonia may never reach the olfactory organ at all, for it is filtered away by absorption in the anterior parts of the nose: if absorption there is eliminated by leading the air current directly to the organ through a hole in the roof of the nose, ammonia produces a violent olfactory discharge which has, incidentally, the very short latency we should expect from a substance highly soluble in water.

One cannot, of course, argue freely from the rabbit to man when the structure of the nose is so much more elaborate in the former, but we must certainly take into account the effect of discharges which may be set up in the fifth as well as in the olfactory nerves when we try to explain olfactory discrimination; and when we consider the flavours of food, the nerves of taste and all the sensory endings in the mouth will be involved as well to give the composite pattern which we recognize as that to be expected from, for example, an anchovy or a banana: and the picture is receiving further elaboration all the time as the result of the movement of air past the fauces and the movements of the tongue and jaws.

It is of some interest to inquire whether this picture is all painted in one part of the brain or whether the different ingredients are sent to different parts of the cerebral cortex and collected together at a later stage. The discharges from the olfactory organ certainly go in the first instance to specialized receiving areas in the ventral parts of the brain; but there is some indication that they are relayed from there to the main sensory receiving area for the nose and mouth on the lateral surface of the cerebral cortex. At all events, the complete picture is an elaborate one even when the smell comes from a remote source and not from inside the mouth.

When we compare our own rather simple olfactory judgments with those of an animal which depends as much on its nose as on its eyes, we see even more clearly how behaviour is guided by complex clues from every available source. The remarkable powers of dogs in following a trail by scent were investigated by Romanes in 1887, and a recent paper by McCartney gives an excellent account of more recent work. One thing that emerges very clearly is that the dog employs his eyes, his nose, and indeed all his powers in following the trail. Unless he is specially trained he may be guided by vision as much as by scent, and the scent which guides him is that of the crushed earth as well as that of the boots which crushed it.

The sense organs which pick all these clues will not have to wait for the environment to provide them. It will be actively scanned by movements of the eyes and ears, by sniffing, turning the head, etc.; and the sensitivity of the organs will be actively adjusted to give the best results, the pupils will be made to dilate or contract and the air entry to the nose will be adjusted by the force of inspiration and the control of the nostrils. All these adjustments will be regulated by the sensory discharges from the organs concerned as well as by the sensory feed-back from the muscles which carry them out.

In fact, the nervous system will be guided by a picture of the largest possible size, each item of which has been actively focused. The neurophysiologist has still a great many problems concerning the individual receptor cells; but the interest is shifting to their collective effect. The problem for the future will be to decide how the nervous system can react as it does to such a picture, how it is recognized and what determines the next step that the organism should take.

POST OFFICE ENGINEERING RESEARCH STATION

'OPEN DAYS'

THE Post Office Engineering Research Station at Dollis Hill was open for inspection during September 27–28, when a large number of representatives of science, industry, the technical press, etc., were invited to visit the Station and view its activities. The Station houses the Research and Radio Experimental Branches of the Engineer-in-Chief's Office of the Post Office Engineering Department, and the greater part of Post Office research work is done there, though other headquarters branches have small development laboratories in which many of their problems are studied. The staff, which at present totals nearly 1,100, is housed entirely in brick buildings erected since 1926, including two administrative blocks, which contain offices and laboratories, and a number of outbuildings in which are laboratories and workshops. The primary purpose of the work at Dollis Hill is to maintain and improve the efficiency of the telecommunication services which the Post Office provides for the public. The Station is consulted on telecommunications problems by other government departments, and some work is done for them. The work at the Research Station is split into seven main Divisions dealing with the following subjects: electronics, materials, mathematics and physics research, radio, switching, telephone and telegraph apparatus (including postal engineering), and transmission.

Two kinds of workshop facilities are provided. There are the central model shops equipped so that most types of apparatus can be made in small numbers; these shops serve all the Divisions and are capable of all kinds of constructional work from metal-welding to high-class instrument-making. Although there is a comprehensive array of machine tools, a certain amount of work is put out to specialist firms. Supplementing the main shops, most Divisions have small workshops in which the laboratory staffs themselves make experimental models and do jobs which are considered too small to be sent to the central shops. These divisional workshops are equipped with suitable hand-tools and a few simple power-tools. The divisional workshop was introduced during the Second World War and is now an important link in the organization. It performs the dual function of relieving the skilled instrument-makers of the need for carrying out many tasks which do not call for their skill, and it removes the laboratory workers' sense of frustration at the delay which sometimes occurs to small jobs in a big shop. Library, technical information and patent services are centralized, and these services are provided for the whole Engineering Department of the Post Office. A small mathematics group provides expert assistance on mathematical problems.

It is usually difficult to estimate the cash value of a research establishment in a commercial concern, and the Post Office Research Station is no exception to the general rule. It is true that some of its developments such as the speaking clock, have been put into service in such a way that a net revenue account can be readily compiled, but much of the result of successful research is tangible only as improvements in the services provided for the public. Typical of a development of this kind is the test set for detecting faulty connexions. It may not be generally realized that speech between people speaking over a single trunk circuit must pass through ten thousand or more connexions in the line equipment alone. Any one of these, if faulty, is liable to cause great annoyance to the speakers and may in the end lead to a loss of revenue. Test sets have now been developed for locating faulty connexions, in the first place, by tracing them to individual units (for example, amplifiers). These testers are sensitive enough to indicate a transmission variation of one millibel (0·01 db.) in magnitude and one millisecond in duration. When the fault has been traced to one unit, another instrument is used to test individual joints and contacts; this indicates short-duration resistance changes of 0·001 ohm.

The Transmission Division is keenly interested in problems relating to submerged repeaters. Shallow-water repeaters such as have been used with success on cables to the Continent since the Second World War are established engineering practice and have obviated the cost of many additional cables. Deep-water repeaters involve new mechanical and electrical problems. Glands to admit plastic cables must be watertight at 4 tons/sq. in., and casings, not too unwieldy to handle on a cable ship, must be designed for this pressure. On the electrical side there are difficulties due to the long lines and the need to run many repeaters in tandem; an amplifier, designed for this service, is unaffected by any single open-circuit or short-circuit in the majority of its components, including valves.

Progress to-day depends a lot on the development of new materials and the improvement in properties or consistency in known ones. To an engineer, consistency is often at least as important as improved properties; it enables him to design more economically without performance falling below prescribed limits. Present-day policy is to concentrate effort on a few selected fields; those of greatest interest are magnetic materials, dielectrics, semi-conductors, plastics and some metals. Grain-oriented materials, both metal and plastic, are of great interest and the importance of germanium in the telecommunications industry is fully realized. Contact problems in switching and connecting devices are also studied.

The work of the Switching Division is at present mainly concentrated on the immediate problem of operator-dialling over trunk circuits; less urgent, but even more important, are the problems of subscriber-dialling over trunk circuits and the long-term study of the application of electronic methods to automatic telephone switching.

A growing feature of the work at Dollis Hill is that connected with the postal service. Statistical studies of the work in sorting offices are leading to important results, and the more precise knowledge gained may make useful improvements in routing possible in the future. Experimental work on the mechanical sorting of mail was started before the Second World War, but was dropped for more urgent matters A new start has been made and an experimental letter-facing machine built, based on photoelectric selection. The general principle of photoelectric scanning is applicable to other purposes, such as the conversion of pencil-stroke codes on white tickets, to other forms, such as punched-hole codes which can be handled by conventional office machinery.

The Electronics Division has made considerable progress in its experimental studies of the factors affecting valve life. The manner in which valves fail is now largely understood, and effort is being concentrated on practical means for eliminating the principal causes of cathode failure, gas poisoning and interface growth. It is also concerned with the performance of crystal diodes and triodes, which are essential for some of the latest developments in communications techniques.

Much of the work in the radio laboratories is directed towards improved overseas radio-telephony services. The single-sideband technique is being more and more used in these services, and a new receiver for this type of signal has recently been developed. Efficient aerials are essential in long-distance services, and there is a group of workers concerned with aerial development. The steadily increasing number of aerials at large radio stations tends to cause congestion, and a model technique using centimetre wave-lengths has recently been brought into use in the investigation of the effects of obstructions upon the directional properties of aerials.

Turning to internal radio communications, the development of microwave systems for the transmission of multi-channel telephone or television signals between large cities continues. Precise information on propagation is necessary in the design of such systems, and several experimental links, over land and over water, are under observation. At the other extreme, radio links are useful for providing single-channel telephone communication with isolated communities, such as live on some of the small islands off the coasts of Britain: a primary-battery-operated, very-high-frequency system for this purpose is on trial. A radio service may be partly or completely upset by interference from electrical machinery or another radio service, and the Post Office tries to minimize such interference by regulation, licensing and technical assistance. In this connexion it is necessary to develop and test interference-measuring sets and to determine the degree of interference that can be tolerated in various radio systems. Recent work includes the determination of the amount of co-channel and adjacent-channel interference permissible in television reception.

Accurate frequency control is necessary in both line carrier and radio communication, and a frequency standard is maintained at Dollis Hill. It includes a number of quartz ring crystals, in improved mountings; these crystals have an outstandingly good performance, and some have been supplied to the National Physical Laboratory and to the Royal Observatory. Equipment similar to that at Dollis Hill has been installed at Rugby radio station to control the standard frequency transmission that the Post Office provides for the Department of Scientific and Industrial Research. The Post Office has recently taken part in international discussions to determine the best form of distress signal for use on 2,182 kc./s. in the marine radio-telephone band, for the operation of automatic distress-signal receivers. A simple device for use with a conventional receiver has been developed; although sensitive, it is remarkably immune to false operation by ordinary speech.

It should be remembered that the whole of the work in Great Britain on civil telecommunication research is not confined to Dollis Hill; all the large manufacturers of telecommunication equipment, radio and line plant have their own research departments where much original work is done. There is also the Radio Research Station at Slough, of the Department of Scientific and Industrial Research. Since the final development stages of equipment which is to be manufactured in quantity are best done in laboratories associated with factories, arrangements exist for the transition from laboratory model to large-scale production to be undertaken by contractors.

APPLICATIONS OF PHYSICS IN THE DIAGNOSIS AND TREATMENT OF CANCER

AMONG a number of scientific and medical gatherings to mark the centenary of the Royal Cancer Hospital, London, S.W.3, the Physical Society held a symposium on the "Applications of Physics in the Diagnosis and Treatment of Cancer" in the Physics Department of the Hospital during October 5–6; Prof. L. F. Bates, president of the Physical Society, took the chair for the first session.

Opening the meeting, Prof. W. V. Mayneord remarked that this was the first occasion on which the Society had met in a hospital and, in doing so, marked yet another stage in the recognition that the applications of physics in medicine now constitute an important branch of applied physics. He gave a brief historical sketch of the influence of the physical sciences on medical thought and practice from early times, and stressed the present need for physicists trained in biology and biophysics.

In his paper on "The Use of High-Energy Particle Accelerators", Dr. D. A. Layne discussed the difficulties of the treatment of deep-seated tumours by normal-voltage X-ray therapy and the ways in which the use of high-energy particle accelerators can help to overcome them. The application of high-energy beams of X-rays and particulate radiation were considered and also the most probable useful energy ranges for each type of radiation. It was emphasized that considerable preparation, both physical and biological, is necessary before any generator of this type can be applied clinically. Each machine has its own special problems, but, as an example, particular reference was made to those encountered in the clinical preparation of the 30-MeV. synchrotron at the Royal Cancer Hospital. Finally, attention was paid to experimental and theoretical work on the process of particle injection into betatron orbits, undertaken in the hope of increasing the X-ray output. It is normally supposed that, for most betatrons and electron-synchrotrons, only 1–2 per cent of the theoretical maximum charge is actually accelerated, but the work described suggests that this theoretical limit has been incorrectly assessed and that the working efficiency is actually nearer 50–100 per cent.

Dr. W. K. Sinclair, in a paper on "The Use of Radioactive Isotopes", spoke of the early hopes of these substances in the diagnosis and treatment of cancer. It was thought that isotopes might be found which become localized specifically in tumour rather than in normal tissue, or in particular organs to the exclusion of other organs, and in specific parts, for example, the nucleus, of the living cell. Unfortunately these hopes have been realized in only a very limited degree, but other ways of using the substances have been found. They have, for example, been localized physically in particular regions of tissue and have provided medical men with a wide range of flexible sources which can be used to treat sites in the body inaccessible to beams of X-rays. The present use of isotopes in the diagnosis of thyroid conditions, skin lesions and brain tumours, and in the treatment of widespread systemic cancer by internally administered phosphorus-32 and physically localized gold-198, and the use of discrete sources in cavities, superficially and interstitially, were considered. Some of the principal physical aspects of these methods were outlined. Concluding, Dr. Sinclair reviewed briefly the principles of localization by external counting, beta-ray and gamma-ray dose estimation, the distribution of dose in tissues in a variety of circumstances, the measurement of beta-ray and gamma-ray sources, and the protection measures necessary in handling the high activities required for therapeutic techniques.

Concluding the first session of the meeting, Dr. R. C. Turner, in a paper on "Electronics", described the part played by this subject in the diagnosis and treatment of cancer, particularly in relation to the development of instruments for the measurement of ionizing radiations. He discussed electronic instruments which have been developed for the control of the radiation dosage delivered to specific sites in and on the bodies of patients undergoing radiation treatment, for the laboratory study and evaluation of new radiation techniques and for the monitoring of personnel and control of levels existing throughout the Royal Cancer Hospital. Various types of direct-reading instruments in routine clinical use were described. An experimental apparatus aimed at presenting a visual image on an oscillograph screen of a distribution of radioactive material or of radiation is in operation, and is yielding some promising results. Dr. Turner discussed the possibility of applying supersonic techniques to the localization of small tumours in specific sites and of its diagnostic significance.

During the evening of October 5 demonstrations were shown in the Physics Department of the Royal Cancer Hospital as follows: scintillation counting; instrument making; physical chemistry; clinical physics and treatment planning; electronics; photographic investigations; isotope investigations; biophysical investigations and autoradiography; and work on high-energy X-rays (30-MeV. synchrotron and 2-MeV. Van de Graaff generator).

Prof. G. I. Finch presided over the second session of the meeting on the morning of October 6, and the opening paper was read by Dr. E. H. Belcher on "Scintillation Counting". He reported that the scintillation counter has found an increasing variety of applications in the field of medical physics during the past three years, by virtue of its high detecting-efficiency for gamma-radiation and the small size of the luminophor used as the detecting element. Dr. Belcher outlined the fundamental principles of the device. The mechanism of production of scintillations varies with the luminophor used, but it is possible to distinguish between pure luminophors such as calcium tungstate in which the emission process is restricted to the luminescent centre, and impurity-activated luminophors such as the thallium-activated alkali halides in which luminescence depends upon the existence of electron-trapping sites in the lattice, which may be remote from the luminescent centre. The design of practical counters for clinical measurements was discussed. It is frequently desirable to separate the luminophor from the photomultiplier tube by a light guide, and in such cases it is often necessary to cool the photomultiplier by liquid nitrogen. Directional and probing counters making use of such techniques were described. Dr. Belcher discussed the absolute sensitivity of scintillation counters. Where a pure luminophor is used, the observed counting-rate may be related directly to the rate of absorption of gamma-ray quanta in the luminophor. In impurity-activated luminophors, on the other hand, the observed counting-rate may be many times greater, because of the phosphorescent emission resulting from the slow release of electrons from trapping sites. Experimental results demonstrating these effects were presented. Further experimental results relating to the luminescence of 'Perspex' and of transparent liquids under gamma-irradiation were also discussed, which suggest that the luminescence of such media may be attributed to the Cerenkov effect. The significance of these results in the fields of biology and radiation chemistry was assessed. Experimental work is in progress on luminescence produced by dissolved radioactive isotopes.

In his paper on "Photographic Measurements of Ionizing Radiation", Dr. G. Spiegler discussed the sensitivity of photographic films per unit of dose as measured by ionization methods, and the sensitivity per unit of absorbed energy. He described the problems involved when a film is used in dosimetric work, emphasizing the energy dependence of the photographic emulsion and the problems of determination of the energy of the incident quanta from the film itself. The chief methods used, such as the 'filter' method and the 'metal foil' method, were described, the former depending upon the absorption in a test filter as indicator of the quality, and the latter making use of the variation with energy of the electronic emission from metal foils. The result of work on the sensitivity of emulsions to beta-particles and investigations on the Ilford *PM*-1 film, used for personnel monitoring, were reported. The absorption of beta-particles in the clothing of personnel, and the relationship between 'tolerance dose' and blackening, were discussed. Dr. Spiegler showed radiographs taken with the 30-MeV. synchrotron, demonstrating the significance of conditions in the high-energy region.

Concluding the meeting, Dr. L. F. Lamerton, in a paper on "Autoradiography", remarked that, when radioactive materials are used either as therapeutic agents or as tracers for the investigation of normal body function, it is always an advantage, and often quite essential, to have precise knowledge of the distribution of the isotope throughout the tissue. The autoradiographic method provides a means of obtaining this information, subject to two main limitations: first, in the preparation of the tissue for autoradiography some of the radioactive material may be lost or its position change; and secondly, when isotopes are used as tracers, the amount of isotope necessary to give a satisfactory autoradiograph may be such as itself to produce biological effects.

Various types of autoradiographic techniques are available, differing in sensitivity and resolution, in general a high resolution being obtained only at the expense of sensitivity. By the use of nuclear emulsions a sufficiently high resolution can be obtained to give information on the intracellular distribution of isotopes, such work so far being done using a Kodak nuclear emulsion, 4 microns thick, in stripping form. However, work is now being carried out on the possible use of more sensitive nuclear emulsions poured over the specimen. In this way, individual electron tracks can be observed for low-energy electrons. This method will undoubtedly be of considerable value for low-energy beta-ray emitters, but its value is problematic for the high-energy beta-ray emitters such as phosphorus-32. An investigation was described which showed the application of various types of autoradiographic technique. This concerned the non-uniform distribution of radioactive phosphate in certain tissues following intravenous administration, and was shown to be due to the concentration of activity on particulate material. It has been shown that the particulate material can arise in the preparation of the active solution and also by allowing the solution to stand in a syringe, unless special precautions have been taken. The non-uniformity of activity resulting may affect considerably the dosage distribution in the tissue.

NEWS and VIEWS

Astronomy at University College, London: Prof. W. C. Allen

A SUBSTANTIAL bequest from the estate of the late Mr. F. Perren has made possible the establishment of the Perren chair of astronomy in the University of London at University College. The chair will be associated with the Observatory at Mill Hill. The first holder of the new chair is Dr. W. C. Allen. Since 1927 he has been on the staff of the Commonwealth Solar Observatory at Canberra. He has also carried out research work at the Solar Physics Observatory, Cambridge, and at Mount Wilson, and later took part in eclipse expeditions to Japan and to South Africa. Prof. Allen has been concerned actively in many different aspects of astronomical research work. He was one of the first to carry out accurate photometric measurement of the Fraunhofer lines in a very thorough investigation, the results of which are still widely referred to as standard. In recent years, Prof. Allen has made many important contributions to the study of solar and terrestrial relations and to solar physics generally. In collaboration with Prof. R. van der R. Woolley he has worked out a theoretical description of the outer region of the sun's atmosphere, and he has been closely associated on the astronomical side with the fruitful developments of radioastronomy in Australia.

Inter-African Bureau of Epizootic Diseases: Mr. W. G. Beaton

UNDER the auspices of the Commission for Technical Co-operation in Africa south of the Sahara, an Inter-African Bureau of Epizootic Diseases is to be set up in Kenya on the site of the East African Veterinary Research Organization at Mugaga, near Nairobi, and Mr. William Gaudenz Beaton, the retiring director of veterinary services, Nigeria, has been appointed director of the Bureau. Mr. Beaton, who has spent his entire career in Nigeria, was born in 1900 and educated at the Royal Veterinary College, London, the Universities of Edinburgh and Liverpool and at the Pasteur Institute, Paris. He entered the Colonial Veterinary Service as a veterinary officer in 1925, becoming a research officer in 1929 and then senior veterinary officer in 1938. In the same year he became deputy director of veterinary services, and in 1948 was appointed director. Mr. Beaton was delegate for Nigeria to the Anglo-French Colonial veterinary conference, held at Dakar in 1946, and in 1948 he attended three conferences: the Colonial genetic conference at Edinburgh, the international rinderpest conference at Nairobi and the United Nations Food and Agriculture Organization conference on rinderpest, also at Nairobi.

Royal Naval Scientific Service: Chief Scientific Officers

THE following promotions to the rank of chief scientific officer in the Royal Naval Scientific Service have been announced:

Mr. J. Anderson, C.B.E., chief scientist at the Admiralty Signal and Radar Establishment, Haslemere. Mr. Anderson was educated at the Royal Technical College, Glasgow. After two years postgraduate training in the Rugby works of the British Thomson-Houston Co., Ltd., he joined the Admiralty Experimental Station at Parkeston Quay, Harwich, in May 1918. Mr. Anderson assisted Prof. R. W. Boyle in the very early stages of the development of Asdic equipment for the detection and location of submarines, and has been associated with the subsequent development of this equipment, first at H.M. Signal School, and later at H.M. Anti-Submarine Experimental Establishment. In 1943 he became chief scientist at this Establishment, which in 1946 was renamed H.M. Underwater Detection Establishment. He went to his present post in May 1951.

Colonel A. V. Kerrison, director of Aeronautical and Engineering Research, Admiralty. After service in France throughout the First World War, and two years on intelligence missions in South Russia, Colonel Kerrison returned to England to work on mathematical analyses of artillery ballistics and anti-aircraft gunnery problems. He eventually became Army liaison officer at the Admiralty Research Laboratory, Teddington, where he initiated systematic research in the development of gunnery fire control. His experimental work on aided laying opened up a new line of development in anti-aircraft gunnery fire control, his design of a close-range predictor based on it being adopted by both the British and United States armies.

Dr. E. C. S. Megaw, director of physical research, Admiralty. After graduation in electrical engineering at Queen's University, Belfast, Dr. Megaw spent two years as a Beit Scientific Research Fellow under Prof. C. L. Fortescue at the Imperial College of Science and Technology, London. His research on valve oscillators at high frequencies was continued after joining the Research Laboratories of the General Electric Company in 1930. Specializing in the study of transit-time oscillators for the highest frequencies, he soon began a long association with what was then the Experimental Department of H.M. Signal School, one of the results of which was that sea-going communication equipment using resonator-stabilized magnetrons was available at the beginning of the Second World War. During the War Dr. Megaw led a team which made many significant contributions to magnetron development, while he was also responsible for the G.E.C.'s part in the war-time studies of centimetric wave propagation. In 1946 he joined the Admiralty, becoming eventually superintendent of research at the Admiralty Signal and Radar Establishment. Recently Dr. Megaw has directed attention to the effect of the turbulent fluctuations of refractive index in the atmosphere on radio wave propagation beyond the horizon.

Exhibition on Wild Life Preservation

THE Zoological Department of the National Museum of Wales, Cardiff, has arranged an exhibition to show how man has affected the wild animals of the world, causing some to become rare and others extinct; and how, in more recent times, he has sought to preserve those in danger of depletion. In the six floor cases are shown examples of birds and mammals which have been greatly reduced or exterminated over much of their former range or exterminated completely. These include the capercaillie, the kite, the marsh harrier, the hen harrier, the ruff, the passenger pigeon, dodo, great auk, as well as the European beaver, pine marten, wolverene, Japanese racoon-dog, aurochs, red deer, roe deer and wild boar. Around the walls are heads of various species of big game, all greatly reduced in numbers and in range by the activities of man. There is also a small wall case containing specimens of twelve kinds of British moths and butterflies which are at present receiving the attention of the Protection Committee of the Royal Entomological Society of London. Those represented in the case are the Clifton nonpareil, large blue, swallowtail, glanville, and heath fritillaries, Sussex emerald, Lewes wave, lunar double-strip, dark-bordered beauty, Blair's wainscot, rose plume and fiery clearwing. Most of the exhibits dealing with conservation are concerned with the national parks, game and wildfowl sanctuaries and other protected areas established in Holland, Denmark, United States, Canada, Africa and Malaya. The exhibition is one of the most comprehensive of its kind which has yet been arranged in Britain and deserves a visit from all those who are interested in wild life. A suitable handbook to illustrate the exhibition, which will be open until February 1952, is available from the Museum.

Quaternary Finds in Belgium

UNFORTUNATELY, no late palæolithic cave art has yet been discovered in Belgium. But at a number of localities small sculptures and engravings on pieces of stone and bone have been found associated with datable industries in the excavations. Such 'home' art is, of course, not an uncommon occurrence in France, and the Belgian examples are, by and large, similar to those already known which have been found in French Magdalenian sites. Representations of a number of different animals, including man, have been found among the Belgian examples, and details are collected in a publication by Prof. François Twiesselmann entitled "Les Représentations de l'Homme et des Animaux Quaternaires Découvertes en Belgique" (Memoire No. 113 de l'Institut Royal des Sciences Naturelles de Belgique. Pp. 28+10 plates. Brussels, 1951). They include *Bos primigenius*, reindeer, ibex, fish, birds and a beetle. Man is also figured, though never as well drawn as are many of the animals. This memoir, as a whole, is an important production; not that it contains much new material, but rather that it brings together in a convenient and well-illustrated form information heretofore only to be found scattered through a number of different publications, many of which are not very easily obtained. The memoir can be recommended to all students of late palæolithic art.

Census of Woodlands in Great Britain

THE first effort at making a systematic census of woodlands in Great Britain was carried out by the Forestry Commission, the results being published in 1928. Much of this survey was done by voluntary workers and was only partially satisfactory. The next census was planned during 1938–39, but had only been partially completed when war broke out. A new census, which would have inevitably been necessary owing to the heavy fellings during the War, was begun in 1947 and the field-work was completed by the middle of 1949 (Forestry Commission: Forest Record No. 3. London: H.M.S.O., 1951). The census had two main objectives: first, to map and classify all the woodlands of the country which are in blocks of five acres and more; and secondly, to obtain an estimate of the timber volume and increment of the woods remaining at the time of the survey—information which is essential for the purpose of regulating future felling, and without which, of course, no working plan could be drawn up. The government forest areas under the Forestry Commission were surveyed by members of the Commission staff, and private woodlands were surveyed by men and women specially recruited and trained for the purpose. This census showed a total area of actual and potential woodland in Great Britain (in blocks of five acres and more) of 3,448,362 acres and about 187,000 acres of small woods less than five acres in extent.

Forestry in Trinidad and Tobago

DURING the past twenty years, the annual reports of the Forest Department of Trinidad and Tobago have been fairly consistent and they have reported good work accomplished in the past; they have been hampered by the need for more roads to open up existing forests and by want of staff due to lack of facilities. The report for 1949 (Port-of-Spain, Trinidad) indicates that the Government has at last realized and sanctioned measures for improvement. Much greater progress may be looked forward to in future years. A reference to the local fauna is of interest. The local fauna of Trinidad and Tobago is largely nocturnal, and although varied and interesting, particularly the mammals and reptiles, are rarely seen by the general public. Hence there is considerable interest in the proposal for the establishment of a zoological garden. Government approval was given in 1947 for the use of a site in the Royal Botanic Gardens, and a Zoological Society was formed in 1947, but further development awaits the incorporation of the Society, which was still pending at the end of 1949. The interests of the local fauna are to a certain extent safeguarded by the Wild Animals and Birds (Protection) Ordinance, under which the conservator of forests is chief game warden; but it is becoming increasingly difficult to enforce the regulations and during 1949 poaching was widespread. This is an interesting report and must be a satisfaction to the conservator of forests, Mr. G. N. Sale, who is leaving the Colony on retirement.

Fish Collections from the Leeward and Line Islands

The George Vanderbilt Pacific Equatorial Expedition of 1951, which was jointly sponsored by the Academy of Natural Sciences of Philadelphia and the California Academy of Sciences, has recently completed a 3½-month cruise through the Hawaiian, Leeward and Line Islands, in which it obtained the largest fish collections as yet taken from the Leeward and Line Islands. The collections are being sorted at the California Academy of Sciences; reports on some of the groups will be made by Robert R. Harry, a graduate student in ichthyology of Stanford University, who was a member of the Expedition during the cruise through both sets of Islands, and other groups will be dealt with by Dr. Earl S. Herald, curator of aquatic biology, Steinhart Aquarium, California Academy of Sciences, who helped in the organization of the biological work and participated in the voyage through the Line Islands. Vernon E. Brock, director of the Hawaiian Division of Fish and Game, took part in the Leeward Islands cruise as the official observer of the territorial government. The Expedition was directed by George Vanderbilt.

German Hydrographic Institute, Hamburg: Report for 1950

The fifth annual report of the German Hydrographic Institute (pp. 70+11 plates; Hamburg, 11: the Institute, 1951) gives an account of its activities during 1950, and is furnished with an extensive appendix which gives very comprehensive details of the publications issued by the Institute and its constituent parts during the year. The Institute, having been rated a 'Federal Superior Authority', was transferred on July 1 of the year to the sole control of the Federal Ministry of Transport. Consequent upon the re-birth of the German merchant fleet, the Department of Nautical Publications and Nautical Notices, in common with the Chart-Producing Establishment, had to meet greatly increased demands, and the same was true of all the Divisions of the Institute directly concerned with shipping requirements—the Tidal Service, the Division of Nautical Astronomy, the Time Service and, in particular, the Department of Nautical Engineering. The Institute's new survey and research vessel *Gauss* was commissioned early in the year, and in summer and autumn she made three cruises in the North Sea devoted to oceanographical and geological-morphological investigations. Among further oceanographical research work were theoretical and laboratory studies of wind-stress effects upon water-level, and investigations of the effects of tidal streams on the structure of the water column and on climate (in the latter connexion a paper by Dr. G. Dietrich was published in *Nature*, 168, 8; 1951). Investigations into the chemistry and geology of the sea were devoted in part to problems of hydrobiology and coast erosion, and in part to problems facing the Ice Service of the Institute. The Geomagnetic Service was occupied with the design of geomagnetic charts to serve the needs of shipping, and with the elaboration of the numerous observations made at the Institute's magnetic observatory at Wingst.

Atomic Scientists Association

The September issue of the *Atomic Scientists News* contains, in addition to a report of the annual meeting of the Atomic Scientists Association, an extract from Sir John Cockcroft's lecture on nuclear power which he delivered at the Naturvidenskabelige Samfund in April and an article by Prof. R. E. Peierls, in which he directs attention to the necessity of not allowing the long-term interests of science and of the community to be neglected in favour of immediate needs. At the annual general meeting of the Association, held in the Clarendon Laboratory, Oxford, on June 30, the main discussion was on the policy to be adopted by the Association towards matters having political implications. Lord Cherwell urged that it should refrain altogether from expressing views on political matters; but Prof. N. F. Mott and several other speakers disagreed and considered it important that the Association should provide, in its *News*, a forum in which such matters could be openly discussed. No formal decision was made; but the president indicated that the newly elected council would take careful notice of the views expressed by both sides. At the meeting, the following were elected to hold office for 1951–52: *President*, Prof. M. H. L. Pryce; *Executive Vice-President*, Prof. Kathleen Lonsdale; *Treasurer*, Dr. L. E. J. Roberts; *Honorary General Secretary*, Dr. J. L. Michiels; and *Editor of the News*, Dr. H. R. Allen.

British Glaciological Society: Officers for 1952

The following have been elected officers for 1952 of the British Glaciological Society: *President*, G. Seligman; *Vice-Presidents*, J. M. Wordie, The Bishop of Portsmouth, Dr. K. Sandford and W. V. Lewis; *Honorary General Secretary*, A. H. Bolitho; *Honorary Assistant Secretary*, D. W. Humphries; *Honorary Meetings Secretary*, D. S. Brook; *Honorary Treasurer*, T. H. Best.

Announcements

The annual conference of the Geographical Association will be held in the Main (Old) Building and the New Building of the London School of Economics, Houghton Street, Aldwych, London, W.C.2, during January 1–4, 1952. In addition, the annual general meeting of the Association will take place at 3.30 p.m. on January 2. Further details can be obtained from the organizer of the conference, Dr. W. G. V. Balchin, Department of Geography, King's College, Strand, London, W.C.2.

J. C. Macrae has been appointed lecturer in gas chemistry in the Department of Coal, Gas and Fuel Industries, University of Leeds.

In the article in *Nature* of Dec. 1, p. 930, on the Royal Dublin Society meeting to mark the centenary of the birth of G. F. FitzGerald, it is stated that photostat copies of the FitzGerald–Heaviside correspondence had been presented to the Society by the Royal Institution. This is incorrect; these copies were presented by the Institution of Electrical Engineers.

RECENT ADVANCES IN ORGANIC FLUORINE CHEMISTRY

By Dr. R. N. HASZELDINE
University Chemical Laboratory, Cambridge

THE preparation of fluoroiodides has enabled many routes of interest in synthetic organic fluorine chemistry to be developed.

Perfluoro esters and lactones. A method for the preparation of fluoroiodides by the interaction of iodine and heavy metal salts of fluoro mono- and di-basic acids has been described in earlier communications[1,2]. Thus $CF_3[CF_2]_nCOOAg$ and $AgOOC[CF_2]_nCOOAg$ with halogens yield $CF_3[CF_2]_nX$ and $X[CF_2]_nX$ (X = Cl, Br, I). The compounds of general formula $X[CF_2]_nX$ (n even) can also be obtained via polymerization of tetrafluoroethylene with iodine (X = I) followed by reaction with bromine or chlorine (X = Br or Cl)[2]. Other products from these reactions are now being identified. Thus, the interaction of iodine and the silver salt of trifluoroacetic acid or of heptafluorobutyric acid can be made to yield small amounts of trifluoromethyl-trifluoroacetate CF_3COOCF_3, and heptafluoropropyl-heptafluorobutyrate $C_3F_7COOC_3F_7$. These compounds, the first completely fluorinated esters to be reported, are believed to arise by a free radical mechanism: for example,

$$CF_3COOAg + I_2 \longrightarrow CF_3COOI + AgI$$
$$CF_3COOI \xrightarrow{\text{heat}} CF_3COO\cdot + \cdot I$$
$$CF_3COOI \xrightarrow{\text{heat}} CF_3\cdot + CO_2 + \cdot I$$
$$CF_3COO\cdot + CF_3\cdot \longrightarrow CF_3COOCF_3\,;$$

rather than by the simple ionic mechanism analogous to that which can be postulated to explain ester formation from hydrocarbon acids:

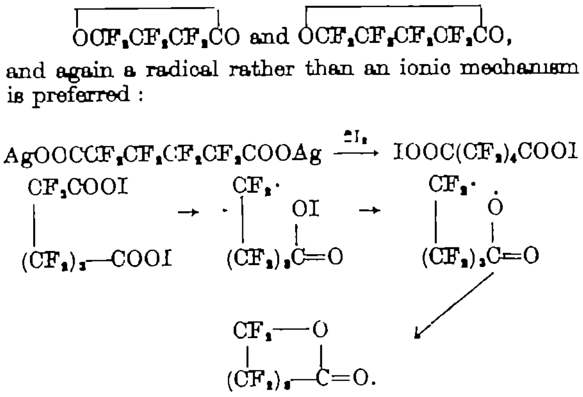
$$CH_3COOAg \xrightarrow{I_2} CH_3COOI \rightarrow CH_3I$$
$$CH_3COOAg + CH_3I \rightarrow CH_3COOCH_3 + AgI.$$

Heterolytic fission of the carbon–iodine bond in CF_3I under the conditions of the reaction is considered unlikely (cf. ref. 4). The properties of these volatile fluoro-esters, which have boiling points near those of the corresponding fluorocarbons, are being investigated.

The silver salts of dibasic acids react with iodine to give perfluorinated lactones as well as fluoroiodides. Thus silver perfluoroglutarate and perfluoroadipate yield

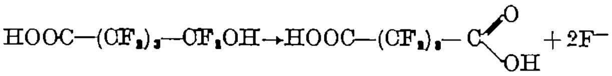
$OCF_2CF_2CF_2CO$ and $OCF_2CF_2CF_2CF_2CO$,

and again a radical rather than an ionic mechanism is preferred:

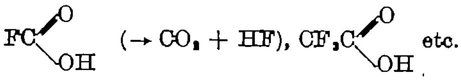


$$AgOOCCF_2CF_2CF_2CF_2COOAg \xrightarrow{2I_2} IOOC(CF_2)_4COOI$$

Although quite stable in a vacuum system, treatment of these lactones with aqueous reagents opens up the lactone rings to give transient compounds containing the $-CF_2OH$ group. These primary hydroxy fluorine compounds are unstable in aqueous media, and the quantitative loss of two fluorine atoms as fluoride ion can be demonstrated:



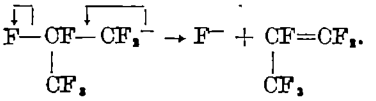
The dibasic fluoro-acid containing one less CF_2 group than the original acid is thus obtained. This indicates that the still unknown primary carbinols CF_3OH, C_2F_5OH, etc., would decompose in aqueous solution to give



The stability of such primary fluoro-carbinols in non-aqueous media is still a matter for conjecture, however, and it may be possible to prepare these compounds from the perfluorinated esters or lactones.

Perfluoro olefins. Sodium trifluoroacetate reacts with iodine on heating to give CF_3I[1]. Sodium heptafluorobutyrate, however, yields C_3F_7I in relatively poor yield and the main product is $CF_3CF{=}CF_2$, the formation of which can be visualized as proceeding by an elimination of the type:

$$CF_3CF_2CF_2COONa \rightarrow CF_3CF_2CF_2^- + CO_2 + Na^+$$



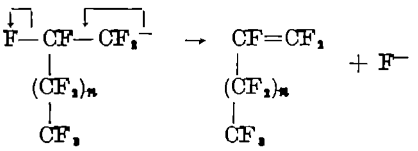
Heptafluoroiodopropane, prepared from CF_3I and tetrafluoroethylene or from C_3F_7COOAg, can be converted into $CF_3CF{=}CF_2$ by means of zinc, and the olefin can also be prepared by the thermal dehydrofluorination of the C_3F_7H obtained from C_3F_7COOH by decarboxylation. Oxidation of the fluoro-olefin gives the acid containing two fewer CF_2 groups than originally, so that one can descend the homologous fluoro-acid series as well as ascend it by fluoroiodide reactions[1,3].

Perfluoro alkyl Grignard reagents. As reported earlier[3], the fluoroiodides $CF_3[CF_2]_nI$ yield Grignard reagents $CF_3[CF_2]_nMgI$. The essential technique for the Grignard preparation is to carry out the reaction in a completely anhydrous solvent such as an ether of suitable boiling point, with a high solvent to fluoroiodide ratio, slight excess of magnesium and operating at a temperature below −30° C.; −50° to −80° C. has been found convenient once the reaction has been initiated at room temperature, or at −40° C. in the case of fluoroiodides with $n \geqslant 1$. Once Grignard formation has occurred, the temperature can be allowed to rise to 0° C. without appreciable decomposition and the compound to be treated can be added at some convenient temperature −60° to 0° C. Alternatively, the compound to be treated can be added after Grignard formation has been initiated and the temperature lowered, so that it is present during Grignard formation and reacts immediately. Yields of up to 65 per cent of the Grignard reagent have been obtained when $n > 1$.

The reactions so far investigated indicate that in the main the fluoro Grignard reagents react like hydrocarbon Grignard reagents. Compounds containing active hydrogen yield $CF_3[CF_2]_nH$; carbon dioxide yields $CF_3[CF_2]_nCOOH$, thus providing a simple method for fluoro-acid formation from longer-chain fluoroiodides (cf. ref. 1). The reactions of CF_3MgI, C_2F_5MgI and in certain instances C_3F_7MgI, with HCHO, CH_3CHO, CH_3COCH_3, C_6H_5CHO, $C_6H_5COC_6H_5$, CF_3COCH_3 and C_6H_5CHO have been found to proceed normally to give the carbinols; appreciable reduction occurs during these reactions, and the nature of the side reactions has not been completely determined. Ketones have been prepared by reaction with CH_3CN, CH_3COCl and C_6H_5COCl; the reactions with CF_3COCl or CF_3CN provide simple syntheses of perfluoro-ketones such as CF_3COCF_3, $CF_3COC_2F_5$ or $CF_3COC_3F_7$.

Elimination reactions of fluorine compounds. Decomposition of the Grignard reagent $CF_3[CF_2]_nMgI$, for example during its formation or on standing, yields $CF_3[CF_2]_nH$, $CF_3[CF_2]_{n-1}CF=CF_2$, MgF_2, MgI_2 and small amounts of the fluorocarbon $CF_3(CF_2)_{2n}CF_3$. The polymerization of the olefin, formed by the suggested elimination mechanism,

$$CF_3(CF_2)_{n-2}CF_2CF_2MgI \rightarrow CF_3(CF_2)_{n-2}CF_2CF_2^- + \overset{+}{Mg}I$$



$$F-\underset{\substack{|\\ (CF_2)_n \\ | \\ CF_3}}{CF}-CF_2^- \rightarrow \underset{\substack{|\\ (CF_2)_n \\ | \\ CF_3}}{CF}=CF_2 + F^-$$

would account for the formation of polymeric material isolated under non-optimum conditions of Grignard formation and reaction. The formation of $CF_3(CF_2)_nH$ could involve an ionic or free radical mechanism:

$$\begin{tikzcd}
CF_3(CF_2)_nMgI \arrow[r] \arrow[d] & CF_3(CF_2)_{n-2}CF_2CF_2^- \arrow[d, "solvent"] \\
CF_3(CF_2)_{n-2}CF_2CF_2\cdot \arrow[r, "solvent"] & CF_3(CF_2)_{n-2}CF_2CF_2H.
\end{tikzcd}$$

It is known that free perfluoroalkyl radicals will abstract hydrogen from solvents at room temperature[5]. The formation of the fluorocarbon $CF_3(CF_2)_{2n}CF_3$ thus probably occurs by a bimolecular reaction

$$CF_3(CF_2)_{n-2}CF_2CF_2MgI + CF_3(CF_2)_nI \rightarrow CF_3(CF_2)_{2n}CF_3 + MgI_2$$

rather than by combination of really 'free' radicals.

The observations in the literature[6,7] that the reactions of CF_3CH_2I or CHF_2CH_2I with magnesium in ether lead to olefin formation and not to Grignard formation may be reinterpreted on the above basis:

$$CF_3CH_2I \rightarrow CF_3CH_2MgI \rightarrow CF_3CH_2^- + \overset{+}{Mg}I$$

$$F-CF_2-CH_2^- \rightarrow F^- + CF_2=CH_2,$$

and similarly

$$CHF_2CH_2MgI \rightarrow F-CHF-CH_2^- \rightarrow F^- + CHF=CH_2;$$

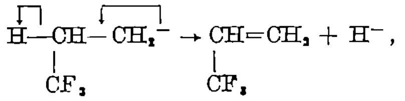
that is, Grignard formation does occur but is followed by decomposition under the unfavourable reaction conditions employed. The reaction of CHF_2CH_2Br with sodium or potassium[8] to give $CHF=CH_2$ can be similarly interpreted. There are indications that the application of the techniques used for the preparation of Grignard reagents from perfluoroalkyl iodides leads to the successful preparation of similar reagents from the dihydro fluoroalkyl halides CF_3CH_2I and CF_3CH_2Br. The carbon–iodine bond in CF_3CH_2I can be broken homolytically to give the $CF_3CH_2\cdot$ radical; the mercurial CH_3CH_2HgI has been prepared.

Application of the silver salt technique[1,2] to CF_3CH_2COOH, a compound prepared by the sequence

$$CF_3CH_2CH_2I \rightarrow CF_3CH_2CH_2OH \rightarrow CF_3CH_2COOH,$$

yields, by reaction with the appropriate halogen, CF_3CH_2I or CF_3CH_2Br.

It is noteworthy that olefin formation occurs only in fluorohalides which have a β-fluorine atom. Thus $CF_3CH_2CH_2I$[9] gives $CF_3CH_2CH_2MgI$, which reacts normally with many functional groups. Olefin formation from this Grignard is unlikely to involve

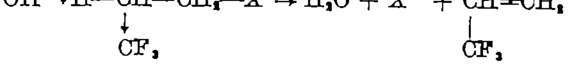


$$H-\underset{\substack{|\\ CF_3}}{CH}-CH_2^- \rightarrow \underset{\substack{|\\ CF_3}}{CH}=CH_2 + H^-,$$

and the $CF_3CH=CH_2$ obtained on heating the Grignard to 100° C. or during certain reactions, for example, with copper or with silver or cuprous halides to produce $CF_3(CH_2)_4CF_3$, is almost certainly formed by free radical disproportionation of two $CF_3CH_2CH_2$ radicals:

$$2CF_3CH_2CH_2\cdot \rightarrow CF_3CH_2CH_3 + CF_3CH=CH_2.$$

The presence of $CF_3CH_2CH_3$ can be demonstrated. Radical reactions to give olefin formation from, say, CF_3CH_2I or $CF_3(CF_2)_2MgI$ are unlikely, since they would involve homolytic fission of a C—F bond. Thus, it may well be that an important reaction of a fluorocarbanion will be to undergo an elimination reaction with expulsion of a β-fluorine atom as fluoride ion. Whereas olefin formation does not occur during Grignard formation from $CF_3CH_2CH_2I$, this fluoroiodide, like other fluoro-halo compounds containing the $CF_3(CF_2)_nCHCX$ unit, readily undergoes dehydrohalogenation with alcoholic alkali. The removal of β-hydrogen as a proton will clearly be facilitated by the electronegative β-$CF_3(CF_2)_n$ group tending to make the β-hydrogen atom relatively more acidic[10], for example,



$$OH^- \; H-\underset{\substack{\downarrow\\ CF_3}}{CH}-CH_2-X \rightarrow H_2O + X^- + \underset{\substack{|\\ CF_3}}{CH}=CH_2$$

Perfluoroalkyl nitroso and nitro compounds. Other reactions under investigation are designed to produce further perfluoro compounds containing functional groups. The synthesis of perfluoroalkyl nitroso and nitro compounds is reported for the first time. Representative members of perfluoroalkyl iodides and di-iodides have been converted into the monomeric blue nitroso compounds, for example, $CF_3(CF_2)_nNO$, and into the nitro compounds, for example, $CF_3(CF_2)_nNO_2$. The reduction of these compounds to the corresponding amines is being attempted.

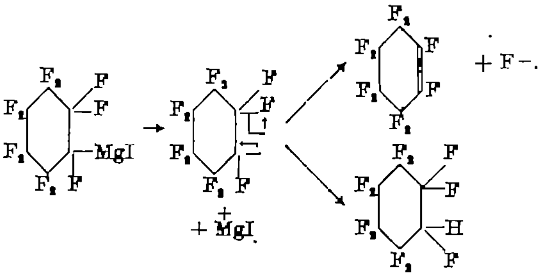
Perfluoro carbinols. The preparation of the carbinols $CF_3(CF_2)_nOH$, $[CF_3(CF_2)_n]_2CHOH$ and $[CF_3(CF_2)_n]_3COH$ by interaction of the perfluoroalkyl Grignard reagents with suitable reagents such as oxygen, perfluoroaldehydes (such as CF_3CHO), perfluoroketones (such as CF_3COCF_3), alkyl perfluoroacetates (such as CF_3COOEt), etc., is believed to have yielded, in specific examples, $(CF_3)_2CHOH$ and $(CF_3)_3COH$, the first completely fluorinated secondary and tertiary alcohols.

Zinc and cadmium perfluoroalkyls. Solutions of zinc and cadmium perfluoroalkyls have been prepared from the perfluoroalkyl iodides CF_3I and C_3F_7I, and as in the case of the Grignard reagents it is noticed that trifluoroiodomethane is the least reactive fluoroiodide. These new organometallic compounds also appear to react like their hydrocarbon analogues, though less readily, and may well prove advantageous (for example, in ketone preparation from acyl chlorides) in avoiding side-reactions found with the Grignard reagents.

Perfluoro acids. Application of the general method for the preparation of fluoro-acids from fluoroiodides has resulted in the synthesis of C_3F_7COOH[*], C_4F_9COOH, $C_5F_{11}COOH$, $C_6F_{13}COOH$, $C_7F_{15}COOH$, $C_8F_{17}COOH$, $C_9F_{19}COOH$ and $C_{11}F_{23}COOH$; derivatives and reactions of these long-chain acids have been examined. The use of the Grignard reagent provides a simpler method for converting fluoroiodides to fluoro-acids. Thus, while it is possible to apply the technique outlined earlier to perfluoroalkyl di-iodides $I[CF_2]_nI$ and hence obtain perfluoro dibasic acids $HOOC[CF_2]_nCOOH$, it is more convenient to prepare the di-Grignard reagent $IMg[CF_2]_nMgI$ ($n > 2$), since this reacts normally with carbon dioxide to give the required acid; reactions of the di-Grignard reagents with other functional groups are being investigated. Monohydro perfluoro acids of general formula $H(CF_2CF_2)_nCOOH$ have been prepared from the monohydro fluoroiodides $H(CF_2CF_2)_nI$ and also by the action of CH_3OH with C_2F_4 under free-radical conditions, isolation of the alcohols $H(CF_2CF_2)_nCH_2OH$, and oxidation of these to the acids.

The reaction of metallic sodium with ethyl trifluoroacetate in ethereal solution yields a mixture of products among which trifluoroacetoacetic ester and trifluoroethanol have been identified. The nature of high-boiling material formed during the reaction is being investigated. The expected diketone $CF_3COCOCF_3$, and the acyloin $CF_3CHOHCOCF_3$, are not formed under the conditions used, and the mechanism of this reaction is clearly of interest.

A perfluoro cyclic acid has been synthesized by the following route. The interaction of hexaiodobenzene and iodine pentafluoride yields, among other products, perfluoro cyclohexyl iodide $C_6F_{11}I$. This iodide yields a Grignard reagent $C_6F_{11}MgI$ which with carbon dioxide gives perfluoro cyclohexane carboxylic acid $C_6F_{11}COOH$ and perfluorocyclohexene C_6F_{10}, the latter arising by decomposition of the acid in aqueous media. It is of interest that the Grignard formation is again accompanied by olefin and by hydro-compound formation (see following reaction scheme). The acid may be converted into the chloride, bromide, or iodide by application of the silver salt reaction, while fluorination of the iodide yields perfluorocyclohexane. Preliminary examination indicates that $C_6F_{11}I$ shows many of the reactions associated with the perfluoroalkyl iodides. The perfluorocyclohexyl radical $C_6F_{11}\cdot$ is formed on heating or on exposure to ultra-violet radiation, and will add to unsaturated compounds. Acetylene, for example, yields $C_6F_{11}CH{=}CHI$, oxidation of which gives perfluorocyclohexene C_6F_{10} and only small yields of $C_6F_{11}COOH$. The oxidation product of perfluorocyclohexene, that is, perfluoro adipic acid, is also formed in substantial amount.



Infra-red spectra of fluorine compounds. The infra-red spectra of many compounds derived from fluoro-acids and fluoroiodides have been taken and will be published in full later. Wave-lengths 'characteristic' of functional groups in fluorine compounds are tentatively assigned in the accompanying table, and may need revision as more samples become available. R_F denotes CF_3, C_2F_5 . . . etc., or C_6F_{11}; the third column of the table gives the values for corresponding hydrocarbons.

R_FCOOH	5·60–5·65	5·85

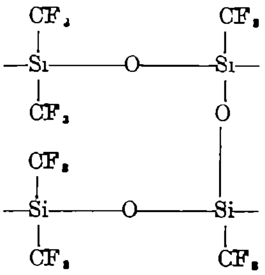
Perfluoroalkyl silicon compounds. It would clearly be of interest if the stability and inertness of fluorocarbons could be combined with the valuable properties of silicones, that is, if fluoro-silicones could be produced. From what is now known of perfluoroalkyl organo-metallic and -metalloidal compounds, it is not at all certain that perfluoro silicones will be resistant to hydrolysis. Two routes have been followed to prepare perfluoro-silicon compounds for examination. In the first, the perfluoroalkyl Grignard reagents have been found to react with $SiCl_4$ to yield a mixture of products from which $(CF_3)_2SiCl_2$, for example, has been isolated; other compounds such as $Si(CF_3)_4$, CF_3SiCl_3, etc., are undoubtedly present. In the second instance, the interaction of fluoroiodides and silicon–copper has been found to yield fluoroalkyl silicon compounds together with disproportionation products. From such compounds it may well be possible to prepare silicones of the type



Even if such polymeric compounds cannot be obtained or should they prove unstable, perfluoro silicon compounds of a different and more suitable type might become possible. Furthermore, it should be emphasized that although fluoroiodides have been used for much of the work described in this and earlier communications, it is distinctly possible that fluorobromo compounds might undergo many similar reactions. There are indications that perfluoroalkyl bromides yield Grignard reagents $CF_3(CF_2)_nMgBr$, and that they can undergo free-radical reactions involving addition to olefins[11].

As the chemistry of fluorine and its organic compounds progresses, it becomes increasingly evident that a vast new field of study is being opened up, a field of chemistry that will eventually considerably supplement the more established field based on hydrocarbon chemistry. [Aug. 24.

LECTOTYPES IN MYCOLOGY: A TAXONOMIC PROPOSAL

By E. J. H. CORNER

Botany School, Cambridge

I WISH to direct the attention of taxonomists to a procedure which is becoming common, at least in the nomenclature of Basidiomycetes. It is the method of proposing types (lectotypes) for genera of more than one species. Such typification is, of course, the goal of generic nomenclature, and the need for it in Basidiomycetes is great, where many highly artificial, untypified assemblages must be combed into homogeneous genera. Typification by a lectotype, however, amounts to generic emendation, inasmuch as species which do not qualify with the lectotype must be excluded. Emendation implies generic and specific revision, comprehensive enough to satisfy modern standards of classification. The scientific approach would be first to revise the genus and its allies, so as to obtain a clear insight into the relationships of the species, and then, in the resultant monograph, to consider lectotypes with the utmost caution in view of the facts that knowledge is always imperfect and that a lectotype once accepted cannot be changed. Unfortunately, the procedure of which I complain proposes the lectotypes first by reference to early (and, scientifically, elementary) publications, without basic revision, without re-definition of genera, even without personal acquaintance with the organisms concerned, and leaves to posterity the real task of evaluating the proposals by study of the species[1-5]. The cart is put before the horse, and, to change the metaphor, the botanist is left in the dark, because fundamental knowledge of the structure of these fungi, on which better classification depends, is so dim. As it is easier to consult libraries than it is to become personally acquainted in microscopic detail with a large number of species, this procedure is becoming a popular expedient to the detriment of mycology. Genera, of course, are not dictated, but are discerned from the study of species.

I will give two examples of the disconcerting consequences of this procedure. They are drawn from the Clavariaceæ and result from the publication of my monograph, which was reviewed in *Nature*[6]. Many more could be cited, especially from the Polyporaceæ. In fact, there must be so many instances of this procedure among cryptogams generally that I hope my proposal will call for approval at the next International Botanical Congress.

Lachnocladium Lév. was described with seven species, none designated as the type. By 1940, it had 113 specific names and was clearly heterogeneous. *L. furcellatum* (Fr.) Lév., as one of the seven, was then proposed as the lectotype, without anything more being known about it than was published in 1830: indeed, none of the original species had been re-described; scarcely any of the whole genus had been described with any exactitude, and there was no attempt to revise the tropical 'clavarias' which are the content of the genus[1,2,4]. In the meantime, I was working on my monograph of the whole family, for the express purpose of modernizing descriptions and discovering generic limits. I interpreted *Lachnocladium* on *L. brasiliense* Lév., another of the seven, because it represented the largest tropical group of species that required generic differentiation, while conforming with the original diagnosis, and because type-material was available in Kew and Paris. In consequence, the genus became the most distinctive and, taxonomically, the most important among all the clavarioid fungi, instead of being the nondescript receptacle for all 'tough' clavarias from the tropics. I deliberately avoided *L. furcellatum* because it was based on three collections (Brazil, Guinea, Bourbon), which were then as inaccessible to me as they had been to others. Now, six years later, through the kindness of Dr. Seth Lundell, of the Institute of Systematic Botany at Uppsala, I have been able to examine the only original collection of *L. furcellatum* that there is in the Friesian herbarium, namely, the Brazilian collection of Beyrich's. It does not belong to *Lachnocladium* emend. Corner; but it is *Lentaria surculus* (B.) Corner [= *Lachnocladium compressum* (B.) Lév.]; and the genus *Lentaria* contains only four of the 113 specific names of *Lachnocladium*, two referring to north temperate species. But what, or where, the Guinea and Bourbon collections of *L. furcellatum* may be is not known, and no mycologist would now assume their identity with the Brazilian merely because the pocket-lens had put them together 120 years ago.

Thus, by reference to 'literature' only, and by putting the cart before the horse, nomenclaturists have advocated as the lectotype of this important tropical genus a species which cannot yet be resolved, which may never be resolved, which may be a mixture of more than one genus, or, if uniform, which represents only 4 per cent of the genus: and this part is not characteristically tropical as the original diagnosis implied. In detail, we do not know whether *Lentaria* is to become a synonym of *Lachnocladium*, in which case *Stelligera* Heim ex Doty takes the place of *Lachnocladium* emend. Corner, or my classification, based on a world monograph, is to be upheld: about fifty species, several of them common, are affected. But, further, if *Lachnocladium* should take over from *Lentaria*, then *Lachnocladium* may easily become a synonym of *Ramaria* or take the place of *Clavariella*, for *Lentaria* is not nearly so clear-cut a genus as *Lachnocladium* emend. Corner. If *Ramaria* should take over *Lachnocladium*, this well-known name of long standing (a hundred years) for tropical species will disappear; if *Lachnocladium* should take over from *Clavariella*, then the names of a hundred more species of temperate and tropical countries will have to be changed, and some of these are the best known of all clavarias. Such doubts, problems and consequences should have been resolved by research into the organisms themselves before the lectotype was proposed, as I did in my monograph before I emended *Lachnocladium* by carefully considering its relations with all other species of the family: no such absurdity as this can enter into my classification. Yet, this blind man's buff, as is the procedure of which I complain, passes as scientific nomenclatorial procedure and may, by reason only of priority, as in this instance, nullify fundamental research, which research would then be used for further nomenclatorial juggling with generic names. The procedure is not merely detrimental to mycology but also contrary to scientific thought, which must exact stability of nomenclature from taxonomy.

The second example is the choice of *P. quisquiliaris* as lectotype of *Pistillaria*, again without monographic revision. My researches showed that the effect of this lectotype was to merge the two large foundation-genera *Pistillaria* and *Typhula* into one and to place a later name, *Cnazonaria*, that has never been current, where *Pistillaria* can readily be maintained, as I have done in my monograph in accordance with Recommendation VI, Art. 18, of the International Rules of Nomenclature (6, 98, 99). Thus, this blind man's buff may also bowl over foundation-genera.

For the sake of scientific research, for mycology, and for botany, which demand stability of nomenclature, I propose to international taxonomists the following principles:

(1) That typification of genera by lectotypes implies generic emendation, which in turn implies revision of the genus and its allies so that the full consequence of the proposed lectotype can be seen; (2) that any such typification without the necessary revision should be rejected.

The proposal is an amplification of paragraph 4 of Appendix 1 to the International Rules of Botanical Nomenclature, as adopted at the seventh International Botanical Congress[7]. It emphasizes what is so often overlooked, especially in connexion with lower plants, that many of the nomenclatorial problems are caused by lack of knowledge of the organisms, which no amount of static typification will improve. In the case of Basidiomycetes, such revision means full hyphal analysis, as explained in the introduction to my monograph, the absence of this analysis being the main source of errors of present-day classifications, whether concerned with lectotypes or not. Thus, if my proposal is adopted, the making of lectotypes will be the outcome of fundamental research, slow but sure, in accordance with the great importance attached to the concept of the generic type. If the proposal is not adopted, there will be so many more of the confusions that I have instanced that many current generic names will become unserviceable in a multiplicity of interpretations, while others will be lost and unfamiliar ones put in their stead.

ACCIDENT PRONENESS

IN a contribution to the eleventh issue of "New Biology"* Dr. R. MacKeith suggests that the idea or hypothesis of accident proneness may turn out to be as important for saving lives as sulphonamides and the antibiotics like penicillin have been.

In Britain there are 1,000 fatal and 350,000 other accidents a year in factories; 5,000 deaths from accidents in the home, and 3,000 deaths and 250,000 injuries on the roads. This can be examined from various aspects. The medical care is expensive. It is wasteful of labour that might be productive. It is the cause of suffering to those bereaved, to the surviving injured and especially to those who are mutilated and scarred. That such a high accident-rate is tolerated appears to indicate that the benefits of having buses, motor-cars and lorries are worth more than are several thousand lives and a quarter of a million injuries a year. Can these accidents be prevented?

In 1919, Greenwood and Woods, working for the Industrial Fatigue Research Board, observed that in a group of workers studied over a period, accidents did not occur uniformly throughout the group, some of the workers had repeated accidents, so that 80 per cent of the accidents happened to 20 per cent of the workers. This ratio has been confirmed by a number of studies of industrial accidents and of road accidents. Such an uneven distribution might arise from a simple chance distribution; but that is not an adequate explanation of the repeated observations. It might be because having one accident makes a person liable to suffer further accidents, or it might be because individuals differ in their liability to accident, even with the same degree of risk.

---

* New Biology, 11. Edited by M. L. Johnson and Michael Abercrombie. Pp. 128+16 plates. (Harmondsworth: Penguin Books, 1951.) 2s.

Thus, in children, the peak age for road accidents is four to six years; children of this age-group have special characteristics, physical, mental and emotional, and these may be responsible for the high accident-rate. Children are active, progressing usually by running rather than walking, and just acquiring the grace in movement which implies full control. They may see a motor-car thirty yards away and not appreciate that it is moving rapidly towards them. They believe that grown-ups are all-powerful and so they may well believe the car could be stopped if necessary. These small children are impulsive and act suddenly and may be moved to action by fantasies or strongly felt emotions. In brief, their high accident-rate may be from their relative physical, intellectual or emotional defects compared with the children of 7–9 who have fewer accidents.

The same possibilities arise when accident-prone adults are studied. An American insurance company's analysis of a series of industrial accidents suggested that "mechanical hazards caused less than 9 per cent, physical and mental defects about 3 per cent, lack of skill less than 8 per cent", leaving personality defects to account for 80 per cent of the accidents.

The idea of accident proneness of psychological origin was first put forward by Farmer and Chambers in a Medical Research Council report published in 1926, and also by Marbe in the same year. Attempts were made to correlate accident proneness with the 'reaction time'. ('Reaction time' is the time between receiving a stimulus and acting upon this perception.) There is little correlation, and though there is a higher correlation with elaborate tests demanding a close co-ordination of stimulus and action, it was not high enough to justify selection of workers on such tests. In dealing with motor-car drivers it was found that failure to do certain psychological tests was reflected in a higher accident-rate. Farmer and Chambers also found that liability to accident is a stable characteristic. Bus drivers with a high number of accidents in their first year of work tended to go on having an excessive number. Inexperience in itself does give a rather increased rate of accidents; but, after the first year, further experience does not reduce the accident-rate. These authors suggested that by taking the results of certain tests and the reports of the accident incidence in the first years of driving, some accident-prone drivers could be detected and perhaps diverted to other occupations.

In the United States Dr. Flanders Durban has made a special study of accident-prone patients, and her work showed that, first, most (80 per cent) of those who have had one serious accident tend to have others, and have a particular kind of personality. The other 20 per cent do not tend to have more accidents and do not have special personality features. Secondly, people with a history of minor accidents are more likely to have serious accidents. If a group of fracture patients is compared with a group of patients with heart disease, 76 per cent of the total illness period in their previous medical history was the result of accidents for the fracture patients, and 2 per cent for the heart patients. Thirdly, accident-prone persons have unusually good health records; they have not been off work much and are especially free of colds and indigestion. Fourthly, they are not clumsy or dull; they are quick-minded "men of action not deliberation', but inarticulate about expressing their feelings. Fifthly, there are various types of accident-prone persons. The most usual type are happy-go-lucky, impulsive, casual people "who divorce and remarry easily". From the psychological point of view they are hostile to authority, but evade this feeling. That is, they are not openly hostile to parents or employers, but take up fatalistic 'don't care' attitudes towards others.

Accident-prone children have pent-up aggression and resentment which is shown by restlessness, stealing, lying or truancy. Fabian and Bendor, studying children of 1–15 years with severe head injuries, found that 38 per cent of them had had previous major accidents, 83 per cent of the children had inadequate parents—sometimes heavy drinkers, sometimes a domineering, abusive father and an over-protective mother. These children are like delinquents; but where one breaks laws, the other breaks bones. The guilty feelings of some of the fracture patients were revealed by remarks such as "It serves me right". Accidents appear to happen when children are doing forbidden things; and it is suggested that some children may be reckless in order to bring punishment upon themselves because they cannot bear the feelings they have of guilt.

Data about accidents in the home are difficult to get. One study suggested that two-thirds of these are due to carelessness of one sort or another. Accidents do happen to the tired and irritable, so that personal rather than structural factors are the main cause of accidents in the home. "But it is clear that there are most injuries where housewives live in overcrowded and ill-equipped homes; they are distracted by the difficulties of keeping an eye on the children while trying to get through the day's work without confusion and disorder. A long story of fighting against the heavy odds of environment often lies behind expressions such as thoughtlessness, carelessness or negligence."

Accident proneness certainly exists in some people. It is not the only factor in the causation of accidents. "Dangerous machines in factories still must be shielded; we must try to improve our roads, and make our homes safer. We must help children to learn safe behaviour. Does the idea of accident proneness offer us any further ways in which accidents might be reduced?"

A transport company transferred their drivers who had most accidents to other jobs and so reduced accidents to one-fifth of what they had been. The ex drivers still suffered injuries, but only to themselves. Most of the fatal road accidents in Great Britain involve public-service vehicles such as buses and lorries, and so it should be possible to know the incidence of accidents, to recognize the accident-prone drivers and persuade them to change to other jobs. This is a field in which trade unions and employers should co-operate, for it may be difficult to work out how such a scheme is to be administered. More should be known about the tests devised for reaction time and the psychological tests which might be used. This would cost money, but not much in comparison with the immense sums proposed for road improvements "to make roads safer". It is unlikely that such expensive schemes will be possible for a long time, and "however much external conditions were improved, with a view to reducing the general accident rate, those specially prone would still have a higher accident rate under all conditions than those with a relatively low accident proneness". If legislation is to be introduced involving limitations on the liberty of the subject, the case for such limitations will have to be very strong before it is acceptable to Parliament.

These would be measures to deal with a situation that has arisen and has been discovered. On a longer-term policy the abnormal reaction to authority shown by the accident-prone should not arise. A child who has repeated accidents should be regarded as having a behaviour problem which needs treatment, and the environment in which the accident-prone personality develops should be removed or altered.

LONDON TO BIRMINGHAM TELEVISION LINK

AT a meeting of the Institution of Electrical Engineers on November 8, a paper entitled "The London–Birmingham Television-Cable System" was presented by T. Kilvington, F. J. M. Laver and H. Stanesby, members of the Post Office Engineering Department. This paper described the cable system which provides channels for relaying television signals simultaneously in both directions between the television broadcasting stations at Alexandra Palace and Sutton Coldfield. The corresponding radio link between these two stations was described in a paper read before the Institution last session under the title "The London–Birmingham Television Radio-Relay Link", by R. J. Clayton, D. C. Espley, G. W. S. Griffith and J. M. C. Pinkham, of the Research Laboratories of the General Electric Co., Ltd., and since published in the *Proceedings* (98, Part 1).

The radio link provides a connexion between the Museum Telephone Exchange in London and Telephone House in Birmingham, with four intermediate repeater stations. Among the conditions of the overall electrical performance, specified by the Post Office, was the requirement that all terminal and repeater stations should work unattended. This feature necessitated the provision of an elaborate supervisory and monitoring system, and the installation of a complete range of standby equipment in all the signal and power circuits of the stations. The frequencies used for transmission in one direction between London and Birmingham alternate at the successive repeater stations between 917 and 937 Mc./s., and the corresponding frequencies used in the other direction are 870 and 890 Mc./s. The aerial system for either transmitter or receiver consists of a dipole with a passive reflector mounted in the aperture of a paraboloidal mirror, 14 ft. in diameter. The gain of such a system is 27·5 db. over a half-wave dipole, and it is shown in the paper that a transmitter power of 6 W. provides a satisfactory signal/noise ratio over the longest links, two of which are slightly less than forty miles. The terminal equipments and their associated circuits were designed to pass television signals over a band 3 Mc./s. wide, with very uniform characteristics of attenuation and phase over this frequency range, while the build-up time of the signal and the overshoot beyond the steady-state response were both required to be very small.

For some time after the opening of the Sutton Coldfield Station in December 1949, this radio link was used for programme transmission between London and Birmingham, and valuable experience was gained on its reliability and operational characteristics. The faults that occurred in a total operating time of four thousand hours arose mainly from electricity-supply failures, from the complexity of the control and monitoring systems, and from the accidental operation of certain keys. From the lessons which are being learned from the installation under service conditions, it seems likely that some simplification of control and monitoring facilities could be introduced into future link-systems for television and telephony.

Reverting to the more recent paper describing the complementary system of connecting by cable the London and Birmingham television stations, the authors explain that the design of the system was largely influenced by the report of the Hankey Committee published in 1945, which looked forward to the time when provision might be necessary for the transmission of very-high-definition colour pictures. Accordingly, it was decided to design the system so that, although initially the limit of the vision-frequency band to be transmitted would be 3 Mc./s., the system could be adapted to a much greater band width without difficulty. The cable route is about 140 miles in length, including the connexions between Alexandra Palace and Sutton Coldfield to the appropriate Post Office exchanges in London and Birmingham, respectively. Provision has been made for repeater stations at approximately three-mile intervals along the route, although at present, with the limited band-width requirement already explained, it has sufficed to equip and use only one in four of these, at a maximum spacing of less than twelve miles.

The vision-frequency signals modulate a carrier of 6·12 Mc./s. at the sending-end, the lower side-band, the carrier and part of the upper side-band being transmitted over the cable. The transmission paths are provided by a pair of coaxial cables approximately one inch in diameter, and, with the repeaters at approximately twelve-mile intervals, the gain and phase delay are substantially constant from 3 to 7 Mc./s. In the event of repeater failure, change-over from working to standby equipment is effected automatically, and power for some of the intermediate repeater stations is supplied over the coaxial cables themselves. The main cable contains four other coaxial cables for telephone channels, and a number of others of the balanced-pair type, several of which are used for supervisory functions. The overall vision-frequency characteristics of the Alexandra Palace to Sutton Coldfield connexion show a total variation in gain of 0·8 db., and in phase delay of 0·04 μsec. for frequencies up to 3 Mc./s. Above this frequency the cut-off is rapid. The performance in respect of linearity, signal/noise ratio and time response is adequate, a fact which is supported by the reproduction in the paper of photographs showing a television test pattern before and after transmission from Alexandra Palace to Birmingham and back, that is, over twice the length of cable normally used in the exchange of programmes between these stations.

It is becoming clear that, in the development of television and telephone systems, large national networks are likely to use both radio links and cables in a mixed cascade arrangement. This association of a trunk radio link with a cable installation in Great Britain will provide valuable experience towards the future planning and development of national and international networks in which both the radio and cable systems will play their appropriate parts.

1,000-Curie Cobalt-60 Units for Radiation Therapy

TELETHERAPY units using radium are limited in usefulness by the low radiation intensities produced by the small amounts of radium which can be used. To secure an adequate dosage-rate, the distance between the source and the tumour cannot be more than a few centimetres, and therefore the dose delivered to the skin lying between the source and the tumour is much higher than that delivered to the tumour. The dose-rate below the surface, expressed as a percentage of the dose-rate at the skin, decreases very rapidly with increasing depth. Thus the percentage depth-dose is influenced primarily by the inverse square law, and one of the chief advantages of high-energy radiation, namely, its small attenuation by the tissue between the source and the tumour, is not realized.

Any attempt to obtain an improvement in the depth-dose by increasing the amount of radium, and correspondingly improving the ratio between the source-to-tumour distance and the source-to-skin distance, is limited by the high cost of radium, and by the required increase in the volume of the source. If the diameter of the source is increased, it is harder to get a well-defined beam; if the thickness is increased, much of the radiation is lost by absorption within the source.

With the high density of neutron flux of the Canadian nuclear reactor at Chalk River, sources of cobalt-60 having specific activities of 20–60 curies per gm. can be prepared. One gram of this isotope will give about the same radiation output as 32–96 gm. of radium. The gamma-rays from cobalt-60 have energies of 1·17 and 1·33 MeV.; thus the average energy is about the same as that of the gamma-rays from a sealed radium source.

Two identical sources of cobalt-60 were made available by the Atomic Energy Project of the National Research Council of Canada in the summer of 1951 for experimental and clinical use. Each source is 1 in. in diameter and half an inch thick, and has an effective strength of 1,000 curies. Two quite different units have been designed to use these sources for radiation therapy.

One of the units, designed by two of us (H. E. J., L. M. B.) for the Saskatchewan Cancer Commission, was installed in the University Hospital, Saskatoon, in August 1951. This unit consists of a steel-encased lead cylinder, with rounded ends, 20 in. in diameter and 22 in. in length, and weighs about 2,000 lb. The source is mounted on the circumference of a wheel near the centre of a head, so that by rotating the wheel it can be brought opposite an opening in one end of the head through which the radiation can emerge. The head is suspended from an overhead carriage. It can be moved in a horizontal direction, raised and lowered, and rotated through 120° in a vertical plane. A rotating circular platform, flush with the floor, is provided for rotational therapy. A variety of treatment fields can be obtained by the use of interchangeable lead diaphragms. Light stainless-steel cones, attached to each of these, indicate the size of the field and fix the treatment distance. Circular fields and rectangular fields up to 20 cm. × 20 cm., at 80 cm. source-to-skin distance, can be obtained.

With the source rotated to the 'off' position, the dosage level 1 ft. from the head is less than 7 mr./hr. With the machine turned on, dosage-levels outside the treatment room, for the severest scattering conditions, are less than 5 mr./hr. Other measurements on this unit were carried out by members of the Saskatchewan group, and details of these will be found elsewhere[1].

The second unit, designed by R. F. Errington and D. T. Green, of the Development Division of Eldorado Mining and Refining (1944), Ltd., is installed in the clinic of the Ontario Cancer Foundation in the Victoria Hospital in London, Ontario. This unit consists of a head pivoted between the arms of a horizontal 'Y', so that it can be rotated downward in one plane through about 105°, that is, from a few degrees above the horizontal to a few degrees beyond the vertical. The horizontal arm can be moved up and down a vertical column by a motor-driven screw mechanism. The vertical column is supported from the floor by a base extending forward under the head.

The radiation beam emerges through a conical opening in the head. When the beam is 'off', this opening is filled with mercury. When the beam is turned on, an air compressor built into the horizontal arm is started, and air pressure forces the mercury up into a reservoir. If the beam is turned off, or if there is a power failure, the reservoir valve opens and the mercury returns, under gravity, to cut off the beam.

Field sizes are varied by means of diaphragms in front of the opening in the head. Four lead blocks at right angles to each other can be adjusted by levers on the outside of the head to yield square or rectangular fields between 4 cm. × 4 cm. and 20 cm. × 20 cm., at 100 cm. from the source. The diaphragm system can be moved along the axis of the beam so that any source-to-skin distance between 70 cm. and 100 cm. can be utilized. In any position, the end of the diaphragm system is 13 cm. or more from the patient. A beam of light from a source at the same distance from the patient as the radiation source, and limited by the diaphragm in the same way as the radiation beam, is used as a field localizer. A detailed discussion of the unit, and of the depth-dose measurements made on it at the Radiology Laboratory of the National Research Council by some of us (National Research Council group), will be found elsewhere[1].

Depth-dose measurements were carried out in Saskatoon and in Ottawa, using D.C. amplifiers with small ionization chambers and water phantoms. The results were in excellent agreement. A summary of the percentage depth-dose data is given in the accompanying table. The maximum dose occurs 5–6 mm. below the surface of the phantom. The surface dose and the dose at any given depth depend on the size of the field. A distance of at least 15 cm. should be used between the limiting diaphragm and the surface of the phantom to reduce the electron content of the gamma-ray beam.

In the first two columns of the table, depth-dose data for the cobalt-60 units, using a 100 cm.^{2} field at 100 cm. source-to-skin distance, is compared with data obtained by Miller[2] for a 2-MeV. Van de Graaff type X-ray unit. In the last two columns a comparison is presented between the cobalt data and measurements obtained by Trump[3] for a 3-MeV. Van de Graaff type X-ray machine, for 100 cm.^{2} fields and for a source-to-skin distance of 70 cm. It is

Depth (cm.)	Field, 100 cm.^{2}. Distance, 100 cm.		Field, 100 cm.^{2}. Distance, 70 cm.	
	Cobalt-60	2 MeV. (ref. 2)	Cobalt-60	3 MeV. (ref. 3)
0·5	100	100	100	100
1·0	99	98	98	98
5·0	80	79	77	76
10·0	58	54	54	53
15·0	41	37	37	36
20·0	29	25	26	25

apparent that the percentage depth-doses for the cobalt are considerably higher than for 2-MeV. X-rays, and slightly higher than for 3-MeV. radiation. This indicates that the average energy of the photons from a 2-MeV., or even a 3-MeV., X-ray generator is lower than the average photon energy of a cobalt-60 source.

The cobalt units are flexible, simple to operate, and should require little servicing. They may prove to be very convenient sources of high-energy radiation for therapy.

The Impossibility of Determining the Sun's General Magnetic Field by Zeeman Effect Measurements

Thiessen[1], v. Klüber[2], and Kiepenheuer[3] have recently achieved a very high accuracy in measuring the Zeeman effect of the Fraunhofer lines. Their results agree that, outside sunspots and other disturbed regions, the Zeeman effect is very small, corresponding to a few gauss or less. From this it is usually concluded that the sun's general magnetic field is less than a few gauss. This conclusion would be legitimate only if there were no turbulence in the photosphere.

Suppose that we observe a certain mass $\int dm$ of the photosphere. The absorption of a spectral line in a mass element dm is proportioned to a function $\beta\,(T)$ which depends mainly on the temperature T. Zeeman-effect measurements in the direction of a z-axis give an *apparent* field H_z:

$$H_z = \frac{\int H \cos\gamma \,.\, \beta\,(T)\, dm}{\int \beta\,(T)\, dm}, \qquad (1)$$

where H is the real field which makes an angle γ with the z-axis.

The field H is the vector sum of the sun's general field H_0 and a turbulent field H_t. From the granulation it can be concluded[4,5] that, in general, $H_t \gg H_0$. As the electric conductivity is so high that the magnetic lines of force are 'frozen in', an adiabatic change of the gas density ρ will, on the average. be accompanied by a change in $H \sim \rho^{2/3}$. As the temperature also changes as $\rho^{2/3}$, H is proportional to T. Hence, if ϑ is the angle between H_0 and H_t, we have:

$$T = \alpha H = \alpha\,(H_0^2 + H_t^2 - 2H_0H_t \cos\vartheta)^{1/2}, \qquad (2)$$

where α is a constant.

Even if β is known, we can evaluate the relation between H_z and H_0 only if we know the turbulence spectrum. Until we do so, no conclusion about H_0 can be drawn from measurements of H_z.

In order to show this by a simple example, suppose that the turbulent field is isotropic, with H_t constant, that $\beta \neq 0$ only for a certain temperature $T = T_a$, and that H_0 is parallel to the z-axis.

The mean temperature T_m is:

$$T_m = \alpha \int_0^\pi (H_0^2 + H_t^2 - 2H_0H \cos\vartheta)^{1/2} \,.\, \tfrac{1}{2} \sin\vartheta d\vartheta.$$

For $H_0 < H_t$ we obtain

$$T_m = \alpha\,(H_t + H_0^2/3\,H_t), \qquad (3)$$

which gives, with $H = T_a/\alpha$:

$$H = (T_a/T_m)\,[H_t + H_0^2/3\,H_t]. \qquad (4)$$

Introducing (4) and $\cos\gamma = (H^2 + H_0^2 - H_t^2)/2H\,H_0$ into (1) we obtain

$$H_z = \frac{H_0}{2}\left[1 + \frac{2}{3}\left(\frac{T_a}{T_m}\right)^2\right] - \frac{H_t^2}{2H_0}\left[1 - \left(\frac{T_a}{T_m}\right)^2\right].$$

For $T_a = 0{\cdot}9\ T_m$ and the $H_t = 3H_0$, we have $H_z/H_0 = -\,0{\cdot}1$.

Although this is a special case, it indicates that we cannot always be sure that Zeeman effect measurements give even the right sign of a weak field.

As $H_t \gg H_0$ does not hold for sunspot fields, there is no serious objection to making measurements of the Zeeman effect of such fields.

From the rate of progression of the sunspot zone, the magneto-hydrodynamic theory of sunspots shows the value of the general magnetic field to be:

$$37 > H_0 > 9 \text{ gauss}.$$

There seems at present to be no valid argument against a dipole field of this order.

I wish to thank Dr. Öhman for stimulating discussions.

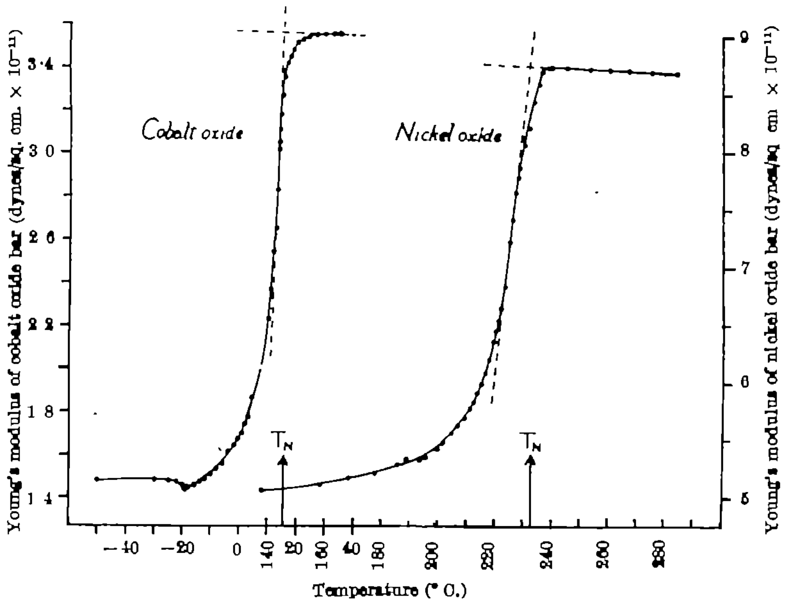
Anomalous Variation of Young's Modulus of Antiferromagnetics at the Néel Point

MEASUREMENTS have been made on the variation of Young's modulus of two antiferromagnetic materials, nickel oxide and cobalt oxide, over ranges of temperature which include their Néel temperatures (the Néel temperature of an antiferromagnetic is that temperature below which antiparallel alignment of the spin vectors of the ions takes place). The specimens of the oxides were in the form of rods of square



cross-section, and measurements of Young's modulus were made by a dynamic method similar to that described by Zacharias[1]. A quartz crystal, cemented to the oxide bars, was used as a generator of longitudinal oscillations.

The measured values of Young's modulus of both bars of oxide as a function of temperature are shown in the accompanying graph. The curves show that for these materials there is a large increase in the value of Young's modulus as the temperature of the specimen is increased through the Néel point. The observed changes of Young's modulus, expressed as a percentage of the lower-temperature values, are about 75 and 150 per cent for nickel oxide and cobalt oxide respectively. An indication of the Néel temperature in each case can be obtained from the point of intersection of the tangent at the point of inflexion with the line drawn through the higher-temperature values of Young's modulus, produced backwards. (This construction is similar to that sometimes employed in the determination of the Curie temperature of a ferromagnetic material from the observed variation of its spontaneous magnetization as a function of temperature.) The values of the Néel temperatures determined in the present work and by other workers using different methods are summarized in the table.

Author	Method	Néel temperature, T_N (° C.)	
		CoO	NiO
Foex (ref 2)	Dilatation	19	250
Trombe (ref. 3)	Susceptibility	19	220–370*
Present work	Young's modulus	16	234

* The form of the susceptibility-temperature curve from which these results are derived is such that an accurate value for the Néel temperature cannot be obtained.

During the course of the measurements, qualitative observations of the decrement of longitudinal oscillations of the oxide bars were made. It was found that for nickel oxide the decrement was relatively high in the range from room temperature to about 160° C., at which point a rapid decrease of the decrement occurred. The decrement remained small from 160° to 300° C., the highest temperature at which measurements were made on this material. Corresponding results for cobalt oxide have not yet been completed.

Two possible explanations of the anomalous variation of Young's modulus through the Néel temperature offer themselves immediately. First, the observed change of Young's modulus may possibly be due to a modification of the shape of the curve of total binding energy of the ions as a function of the inter-ionic distance, due to the additional contribution of the super-exchange energy which appears below the Néel point. However, considering that the super-exchange energy is about 0·03 eV. and 0·05 eV. for cobalt oxide and nickel oxide respectively, compared with the total binding energy of about 2 eV., this explanation appears unlikely. Secondly, the change in Young's modulus may be due to the influence of an applied stress on the preferred orientations of the spin vectors in the antiferromagnetic domains. Experiments designed to test the latter hypothesis are now being carried out in this laboratory, and it is hoped to publish further details at a later date.

Our thanks are due to Dr. G. L. Miller, of Murex, Ltd., who manufactured the oxide bars, to Dr. J. H. Mitchell, of Ericsson Telephones, Ltd., for the quartz crystals, and to Imperial Chemical Industries, Ltd., for the provision of a primary frequency standard.

Charge-Renormalization accompanying Radiative Corrections

THE usual formalism of quantum electrodynamics[1,2] consists in the elimination from the Schrodinger equation of the free particle Hamiltonian H_0 and of the particle interaction Hamiltonian H^i. The resulting Schrödinger equation gives the corrections to the motion of the interacting particles due to their presence in an external field Hamiltonian H^e.

In some cases one is able to introduce a 'bound interaction representation' by eliminating H_0 and H^e. The resulting Schrodinger equation gives the correction to the motion of non-interacting particles in the external field due to their interactions. In this representation operators and commutators depend on the external field[3,4]. The vacuum expectation value of the current-operator $[j_\mu]_0$ represents the vacuum polarization by the external field[4,5].

If $[j_\mu]_0$ is zero, Dyson's graphs[1] are to be used; but the graphs of scattering of an electron by an external field do not exist in the 'bound interaction representation'. One can then infer that only mass-renormalizations and photon self-energy regularizations are to be performed[1-4]. This is the case of a free particle and of an electron in a homogeneous and constant magnetic field. This result explains the absence of charge renormalizations in various works on the magnetic radiative corrections developed in the 'bound interaction representation'[5,7-9].

If $[j_\mu]_0$ is not zero (Coulomb field, variable magnetic field), the 'bound interaction representation' cannot avoid charge renormalizations, for, in addition to the Dyson graphs, one must consider similar terms containing $[j_\mu]_0$. These terms of vacuum polarization introduce again charge infinities.

The 'bound interaction representation' indicates the connexion between charge infinities and vacuum polarizations in quantum electrodynamics. In meson theory, since the meson self-energy must not be regularized to zero, the situation is different.

Another advantage of this representation consists in the fact that one is no longer obliged to develop radiative corrections in powers of the external field.

The case of a homogeneous and constant magnetic field can be treated completely, since the operators and anti-commutators are known exactly for such a field[10,11]. The self-energy in the square of the coupling constant gives a mass renormalization term and a term which is the total magnetic radiative correction. For an electron this term is finite. The development in powers of the magnetic field converges very rapidly. The ratio of the magnetic polarizability to the magnetic moment is of the order 10^{-14}. This result has already been obtained by Gupta[8].

For nucleons with pseudoscalar coupling the terms are finite and converge more rapidly. The ratio of the magnetic polarizability to the magnetic moment is of the order of 10^{-21}. The perturbation method with the external field is thus correct.

Similar calculations for self-energies in the fourth power of the coupling constant are being made. The results mentioned above will be published in detail elsewhere.

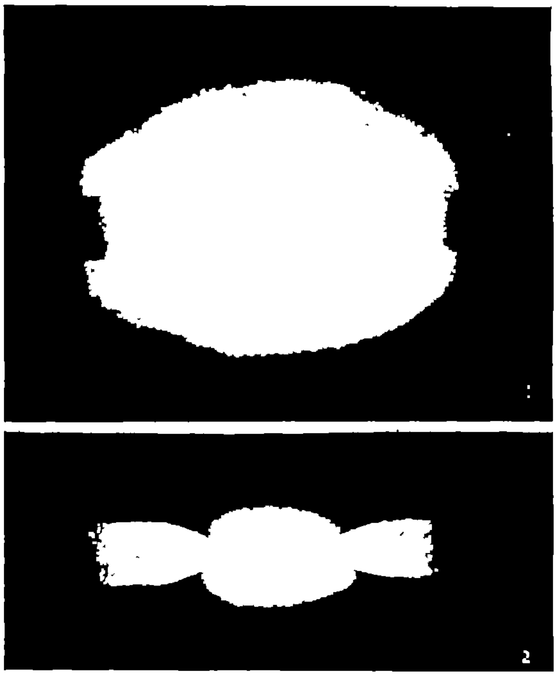
A Discharge Illuminant for Optical Systems capable of either Continuous or Flash Operation

It is sometimes desired to illuminate an object in an optical system at one level for general examination and at a momentarily higher level for photographic recording. The development of a combined flash and continuous source lamp offers a novel method for doing this. The high-pressure mercury-vapour compact-source lamp, the characteristic high brightness of which is well known, has successfully been used under pulse conditions to provide high levels of illumination for high-speed ciné photography[1,2]; this type of lamp has also been used as a condenser flash-discharge source to give high-intensity short-duration flashes of light. Recently a small xenon discharge lamp has been developed which provides a useful amount of light for such purposes as photomicrography, and can, in addition, be switched at will from the steady arc to a condenser flash-discharge with a flash duration of less than 50 microsec. The xenon discharge gives excellent colour rendering under both conditions of operation.



Arc discharge of type *F.A.5* lamp at 150 W. steady rating

In an experimental form, the arc tube is a cylinder of hard glass with an electrode sealed into each end, to form an arc gap of several millimetres. The tube contains xenon at a pressure of about 1 atmosphere, and when operating continuously at 150 watts the light source is 4–5 mm. long and 2·5 mm. wide with a maximum brightness of about 1,000 stilb.

The lamp is designed to discharge 200 joules from a condenser at intervals of about 5 sec., and from Fig. 1 it will be seen that the source size is then larger than the continuous burning source (Fig. 2); but due to the very high current density in the flash (several thousand amperes) its peak brightness is extremely high.

The lamp operates as a steady light source from the normal 200/250 V. A.C. supply with a series choke. For flashes, a condenser charged to between 2 and 2·5 kV. is used, and the lamp is triggered by applying a pulse of 5–8 kV. to a spiral grid placed outside the tube; this also initiates the continuous arc.

Apart from the simple method of control, and the ease of aligning a flash discharge source by the continuous operation of an arc between the same electrodes in an optical system, this lamp provides an electrical means of changing from one type of light source to another in place of the mechanical turret-head system. This type of lamp has also been used as a high-speed compact stroboscopic source, with a mean rating of 125 watts and a repetition frequency exceeding 160 flashes per second.

We are indebted to Mr. L. J. Davies, director of research, British Thomson-Houston Co., Ltd., Rugby, for permission to publish this letter.

Theoretical Determination of Electron Density in Organic Molecules

A recent communication under the above title[1] prompts us to put on record some recent results which we have obtained.

(1) One of us (N. H. M.[2]) has made detailed calculations of the actual electronic density in benzene at points in the molecular plane and in a parallel plane chosen to exhibit the influence of the π-electrons as much as possible. It appears that, except for certain small regions just above and below the carbon atoms, the contribution from the σ-electrons exceeds that from the π-electrons everywhere, and often by a large factor. It appears almost correct, therefore, to describe the π-electrons as imbedded in a denser 'sea' of σ-electrons. These calculations used both conventional molecular-orbital functions and a new solution of the Thomas–Fermi equation. Theoretical discussions of the density exclusively in terms of π-electrons, and without due recognition of the σ-electrons, are likely to lead to quite false conclusions. This is in keeping with recent work of Dr. S. L. Altmann[3] at King's College, who shows that $\sigma - \pi$ resonance is important even in the ground-state of aromatic molecules.

(2) Another of us (P. W. H.[4]) has studied the effect of molecular vibration on the peak densities likely to be recorded by X-ray analysis. The charge-cloud for a non-vibrating atom can be computed wave-mechanically. If we suppose, as a first approximation, that the atom carries this charge with it as it vibrates, then a 'smearing-out' occurs. The peak density in the vibrating molecule is drastically reduced below its value in the non-vibrating molecule. Thus it is highly dangerous to compare the observed (that is, vibrating) density with that calculated (usually non-vibrating). This is also true, though in a reduced manner, for the bridge values of the density in the centres of the various C—C bonds. In addition to this, X-ray measurements are made on a crystal, and it appears that translation and libration of the molecule as a whole significantly change the density distribution in each unit cell. Theoretical analysis of the observed distribution shows that these latter motions are much more important than the internal vibrations in affecting the charge density.

(3) In conclusion, it seems desirable to point out that present X-ray observations, such as those of Abrahams, Robertson and White[5], give the density only at points in the molecular plane. Here, on account of their nodal plane, the π-electrons contribute nothing at all to the density except as a result of fairly large molecular vibrations. It appears from Dr. Klement's letter[1] that he has studied only the π-electrons. If that be so, then what he calls the exchange density in a bond may be shown to be closely related to the conventional π-bond order. Direct check with observation (other than with bond-lengths[6]) cannot be made until Prof. J. M. Robertson uses his X-ray measurements to calculate the density in a parallel plane. Even then, as shown above, the π-electron distribution will be confused by that from the σ-electrons.

A New Type of Organo-Iron Compound

Numerous investigators have studied the reaction of Grignard reagents with anhydrous ferric chloride, but have failed to isolate any organo-iron compounds or to produce any definite evidence for their formation in such reactions.

The statements by Job and Reich[1] and by Champetier[2], that they have obtained stable ethereal solutions of compounds of the type RFeI by reaction of ferrous iodide with organo-zinc halides, are based solely on the formation of ferrous hydroxide on hydrolysis, and may be accounted for by the difference in solubility between ferrous and zinc hydroxides. Indeed, the evidence of Champetier's own experiments with Grignard reagents[2] suggests that such intermediates may be formed at low temperature, but are quite unstable above – 40° C. The normal reaction leads to reduction of the ferric salt and, with excess Grignard reagent, results in the formation of metallic iron according to the equation :

$$6\,R\text{MgBr} + 2\,\text{FeCl}_3 \rightarrow 3\,R_2 + 2\,\text{Fe} + 3\,\text{MgBr}_2 + 3\,\text{MgCl}_2.$$

This reaction is of preparative value and has been shown to yield diphenyl from phenylmagnesium bromide in almost quantitative yield[3].

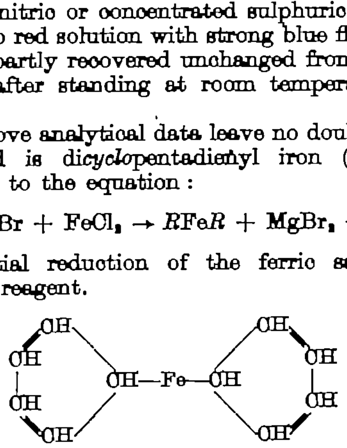
As a possible route to 'fulvalene'[4], we attempted to apply this reaction to *cyclo*pentadienylmagnesium bromide. To a solution of this Grignard reagent (from 18 gm. ethyl bromide and 4 gm. magnesium in benzene with 11 gm. *cyclo*pentadiene) was added an equivalent amount (9·05 gm.) of ferric chloride dissolved in anhydrous ether. After allowing the mixture to stand at room temperature overnight, it was refluxed (1 hr.) to ensure complete reaction, cooled and decomposed with ice-cold ammonium chloride solution in the usual manner. Evaporation of the dried organic layer yielded an orange solid (3·5 gm.). This was moderately soluble in ether, readily soluble in benzene and crystallized from methanol in large needles of melting point 173–174° C. (found : C, 64·6 ; H, 5·6 ; Fe, 30·1 per cent ; molecular weight, by cryoscopic determination in benzene, 186·5. $C_{10}H_{10}Fe$ requires : C, 64·6 ; H, 5·4 ; Fe, 30·0 per cent ; molecular weight, 186·0). Iron was determined gravimetrically as Fe_2O_3 after heating the compound with concentrated nitric acid under a reflux condenser.

The substance sublimes readily above 100° C. It is insoluble in, and apparently unattacked by, water, 10 per cent caustic soda and concentrated hydrochloric acid even at the boiling point. It dissolves in dilute nitric or concentrated sulphuric acid forming a deep red solution with strong blue fluorescence, but was partly recovered unchanged from the latter solution after standing at room temperature overnight.

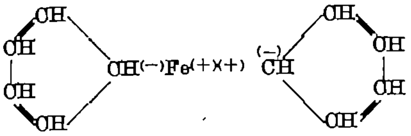
The above analytical data leave no doubt that this compound is di*cyclo*pentadienyl iron (I), formed according to the equation:

$$2\,R\text{MgBr} + \text{FeCl}_3 \rightarrow R\text{Fe}R + \text{MgBr}_2 + \text{MgCl}_2,$$

after initial reduction of the ferric salt by the Grignard reagent.



I



II

The remarkable stability of this substance is, of course, in sharp contrast to the failures of earlier workers to prepare similar compounds and must be attributed to the tendency of the *cyclo*pentadienyl group to become 'aromatic' by acquisition of a negative charge, resulting in important contributions from the resonance form (II) and intermediate forms.

Our studies of this reaction and of other approaches to fulvalene are continuing.

Activated Adsorption of Hydrogen on Nickel Catalysts

The thermodynamics and kinetics of the chemisorption of hydrogen on metals are of considerable importance for the elucidation of the mechanism of hydrogenation reactions catalysed by these metals. Although extensively studied, the process still remains rather obscure because the evidence is in many respects conflicting. O. Beeck *et al.*[1] and E. K. Rideal and B. M. W. Trapnell[2], for example, report that, working with metal films such as nickel, the adsorption velocity is immeasurably rapid. Only a small amount of the hydrogen adsorbed shows a measurable rate of adsorption. Increasing the temperature of adsorption causes a considerable decrease in total adsorption, which is ascribed to the combined effects of desorption and sintering. However, the amount of hydrogen slowly adsorbed remains about the same. They consider the slow process to be a solution of the hydrogen in the nickel structure.

On the other hand, experiments performed on reduced nickel compounds show a different result, as reported for the first time by A. F. Benton and T. A. White[3] and since then confirmed by numerous authors, for example, quite recently by H. Sadek and H. S. Taylor[4]. Although a certain part of the adsorption is again very rapid, quite a considerable amount is adsorbed slowly. The remarkable effect is observed that the amount of adsorbed hydrogen increases with increasing temperature, which has led H. S. Taylor to the supposition that the adsorption is 'activated'. The transition from rapid to slow adsorption was explained by assuming heterogeneity of the surface. It may be remarked in this connexion that the tendency to sinter in many of the preparations tested was less pronounced than in the case of the films; hence a process may here be observed which remains unobservable in the films as a result of sintering.

Studying these phenomena on a catalyst consisting of 100 parts of nickel to 29 parts of silica (by weight), obtained by co-precipitation from nickel nitrate, sodium carbonate and sodium silicate solutions and subsequent reduction, we were able to reproduce both types of behaviour. The all-important parameter in this connexion proved to be the temperature of reduction. After reduction at a temperature lower than 400° C. the sample obtained was comparable in behaviour to those described by the second group of workers. If, however, the temperature was higher than 500° C., the ensuing sample closely resembled the films, with the difference that the tendency to sinter was very much reduced.

For this type of nickel – silica catalyst, reduction is incomplete below 400° C., but substantially complete above 500° C. The obvious inference is therefore that the oxygen content of the metal obtained is responsible for the activated adsorption, presumably because part of the surface is covered by oxygen, a suggestion first put forward by J. K. Roberts[5]. An attempt was therefore made to prove this point by careful adsorption of oxygen on the surface of a well-reduced catalyst. The oxygen was adsorbed at − 196° C., the oxygen-covered sample slowly heated to a higher temperature and thereafter the adsorption of hydrogen determined. The results confirmed Roberts's hypothesis. With increasing amounts of oxygen coverage, the amount of rapidly adsorbed hydrogen decreased while the total adsorption remained more or less constant.

A very interesting phenomenon was, moreover, revealed by these experiments. The decrease of rapidly adsorbed hydrogen with the oxygen coverage was linear, but *two* relationships were found, depending on the temperature of preheating of the oxidized sample. If this temperature was 400° C.:

$$V_{\mathrm{I,H_2}} = C - V_{\mathrm{O_2}};$$

if it was 100° C.:

$$V_{\mathrm{I,H_2}} = C - \tfrac{1}{2}V_{\mathrm{O_2}},$$

where $V_{\mathrm{I,H_2}}$ is amount of hydrogen rapidly adsorbed (cm.^{3}); $V_{\mathrm{O_2}}$ is amount of oxygen presorbed (cm.^{3}); C is a constant.

Assuming hydrogen to be adsorbed as atoms, one might explain these relations by the supposition that oxygen is chemisorbed as molecules at low temperatures, but dissociates to adsorbed atoms at high temperatures.

It may be remarked that the total hydrogen adsorption remains practically the same in both cases.

Any procedure which results in heating a reduced catalyst sample at high temperatures (~ 400° C.) without hydrogen being present, for example, heating under nitrogen or even prolonged high-vacuum pumping at these temperatures, causes the rapid adsorption to decrease while at the same time some sintering is observed. Renewed reduction restores the rapid adsorption. Consequently, some process of surface oxidation occurs during this heat treatment. It may be that a diffusion of oxygen atoms from the interior of the metal to the surface occurs; but it is more probable that the silica carrier releases water which reacts with the metal:

$$Ni + H_2O \rightarrow NiO + H_2,$$

either on the surface or in bulk or both.

To our mind the experiments described here fully confirm Roberts's hypothesis on the nature of the activated adsorption. Activated adsorption as defined by H. S. Taylor accordingly is adsorption on that part of a metal surface which is covered by oxygen atoms or molecules. The phenomenon hence cannot be considered as evidence for the heterogeneity of a pure *metal* surface.

The experiments reported here will be published in full in the *Recueil des Travaux Chimiques des Pays-Bas*.

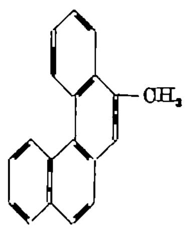
A Novel Synthesis of 2-Methyl-3 : 4-Benzphenanthrene

It has been observed that 2-methyl-3 . 4-benzphenanthrene[1,2] is a potent carcinogenic hydrocarbon[3]. Although this hydrocarbon was synthesized previously by Hewett[1] and by Newman[2], their methods are rather laborious and involve numerous steps, and eventually make this hydrocarbon less accessible to synthetic chemists. However, the method developed in this laboratory for synthesis of polycyclics[4,5] was extended to the synthesis of the above hydrocarbon. The synthesis of 9-methyl-phenanthrene[6] served as a model for this synthesis, which gave 2-methyl-3 : 4-benzphenanthrene in excellent over-all yield in four steps starting from 2-allyl-1-tetralone.



α-Tetralone was formylated to 2-formyl-1-tetralone (boiling point 136–138°/5 mm., lit.[7] boiling point 154°/10 mm.) following the conditions of Birch and Mukherji[8]. Allylation of this compound was effected with allyl iodide in presence of dry sodium ethoxide in benzene to give 2-allyl-2-formyl-1-tetralone (boiling point 134–138°/1 mm.). This substance was hydrolysed to 2-allyl-1-tetralone (boiling point 144–150°/5 mm.; semicarbazone, melting point 174–175°) by mechanical stirring with 5 per cent sodium hydroxide at 50–55° C. for 3 hr.[8]. 2-Allyl-1-tetralone was then subjected to aluminium chloride-catalysed reaction[4,5] with benzene, when 2-(β-methyl-β-phenylethyl)-1-tetralone (boiling point 200–208°/4–5 mm.) was obtained in satisfactory yield. Reduction of this substance with aluminium *iso*propoxide and *iso*propyl alcohol gave the corresponding carbinol (boiling point 205–210°/4–5 mm.) in almost quantitative yield. This carbinol was cyclized with concentrated sulphuric acid[10]. (1·84) to 2-methyl-1 : 2 . 9 : 10 : 11 : 12-hexahydro-3 : 4-benzphenanthrene, which distilled at 2 mm. from a bath at 195° C. This hexahydro derivative was smoothly dehydrogenated with palladium-charcoal (30 per cent) at 300–320° C. for 4 hr. to give 2-methyl-3 : 4-benzphenanthrene, as a pale yellow viscous oil, which crystallized from acetone-alcohol in small, almost colourless needles (melting point 71–72° C.; calc. for $C_{19}H_{14}$: C, 94·2; H, 5·8; found: C, 94·07; H, 5·9 per cent; lit.[1], leaflets, melting point 69·5–70° C.; lit.[2], almost colourless needles, melting point 70·4–71° C.).

The hydrocarbon gave a vermilion picrate which crystallized from alcohol in needles (melting point 135–136° C.; lit.[1], melting point 132·5–133·5° C.; (calc. for $C_{19}H_{14}C_6H_3O_7N_3$: C, 63·7; H, 3·6; N, 8·91; found: C, 63 13; H, 3·51; N, 8·75 per cent).

The microanalyses were carried out by Drs. G. Weiler and F. B. Strauss (Oxford).

Colour Reagents for the Paper Chromatography of Di- and Tri-hydroxy Phenols

Various colour-producing spraying reagents have been developed for the detection of di- and tri-hydroxy phenols on paper chromatograms. Excellent results are obtainable with the diazotized sulphanilic acid of Evans, Parr and Evans[1] and the phosphomolybdic acid reagent of Riley[2]. Bate-Smith[3,4] applied Partridge's[5] ammoniacal silver nitrate reagent for furnishing diagnostic evidence regarding the position and number of hydroxy groups and also used ultra-violet light, both in the presence and absence of ammonia vapour, to obtain useful information. The majority of the above class of C_6 compounds give characteristic coloured spots with a 2 per cent aqueous ferric chloride spray[3,4], although meta- and para-hydroxy phenols (for example, orcinol, phloroglucinol, resorcinol and hydroquinone) show ill-defined greyish spots.

In the present communication a new spray reagent, developed during a comparison of the complex phenolic mixtures formed by the alkaline degradation of the extracts of the bark of *Acacia mollissima* Willd. (black wattle tannin), *A. decurrens* Willd. (green wattle tannin) and *A. dealbata* Link. (silver wattle tannin), is described. Numerous phenols have been used for the identification[6,7,8] and estimation[9] of sugars; but the reverse, that is, the use of sugars for the identification of phenols, appears to have found little application, except in the case of a fructose – hydrochloric acid reagent for the identification of resorcinol[5].

Sucrose (2·0 gm.) was therefore shaken with a mixture of concentrated hydrochloric acid (10 ml.) and absolute ethanol (90 ml.). Complete solution was not achieved, but the resulting mixture, when lightly sprayed on to paper chromatograms of di- and tri-hydroxy phenols and heated for 40–60 sec. at 85–95° C., gave the colorations shown in the accompanying table in ordinary and ultra-violet light.

Phenol	Visible light	Ultra-violet light
Catechol	Violet	Blue-violet
Pyrogallol	Dark-pink	Violet
Resorcinol	Light-pink	Weak yellow fluorescence
Phloroglucinol	Brown-pink	Maroon
Orcinol	Light pink fading to yellow in 1–2 hr.	Light blue fluorescence
Hydroquinone	Grey	Violet

Variations in concentration produce slightly different shades of colour. Of the above, catechol and hydroquinone require slightly longer heating periods (about 60 sec.) before their characteristic colours appear. The hydrochloric acid – sucrose – ethanol reagent affects the paper only to a slight degree, as very light spraying and short heating times are necessary. Phosphoric acid, while not affecting the paper[9] when used to replace the hydrochloric acid, gives similar but weaker colorations. Orcinol spots when sprayed with sucrose – phosphoric acid – ethanol show more intense light-blue fluorescence under ultra-violet light.

Fructose may be used in place of sucrose in these reagents, since both give the same colorations when sprayed with resorcinol or naphthoresorcinol in the presence of hydrochloric acid[6] or phosphoric acid[9]. A cheap and easily made reagent capable of giving clearly defined characteristic colours with various polyhydroxy phenols is thus available.

Chromatographic Detection of Pyruvic, Dimethylpyruvic and α-Ketoglutaric Acids in Cultures of *Aspergillus niger* on Various Substrates

Ramachandran and Walker[1] have shown that, in Hida's medium of inorganic salts[2], preformed felts of *Aspergillus niger* produce pyruvic and dimethylpyruvic acids from xylose or from glycerol, and that addition of sodium acetate to the glycerol medium enhances considerably the yield of both these keto-acids.

We have now found that when preformed felts of *A. niger* are allowed to float upon a sterile solution of potassium arsenite (0·01 *M*) in 0·1 *M* phosphate buffer (*p*H 8·0) at 30° for 12 hr., the mould produces from its reserve material, substances which yield derivatives with 2 : 4-dinitrophenylhydrazine. Examination of these products by paper chromatography according to the procedure of Cavallini, Frontali and Toschi[3] has shown that the metabolism solution contains pyruvic acid, dimethylpyruvic acid, α-ketoglutaric acid, a fourth keto-acid which is neither acetoacetic acid nor α-ketobutyric acid, and a non-acidic carbonyl-containing substance. Krebs and Eggleston[4] demonstrated the formation of α-ketoglutaric acid in pigeon's breast muscle in the presence of arsenite, and the conversion of glucose to the same acid by *Pseudomonas fluorescens* was described by Lockwood and Stodola[5]. α-Ketoglutaric acid has also been obtained by the action of *A. oryzae* on glutamic acid as reported by Uemura[6], and, hitherto, this has been the sole mention of the production of this keto-acid by mycological activity. The spot on the chromatogram which represents the 2 : 4-dinitrophenylhydrazone of the unknown keto-acid lies between the positions occupied by the respective derivatives of pyruvic and dimethylpyruvic acids. The different R_F values found by us for authentic 2 : 4-dinitrophenylhydrazones of keto-acids and for the several 2 : 4-dinitrophenylhydrazones obtained from the metabolism solution of the mould are shown in the accompanying table.

SOLVENT: BUTANOL SATURATED WITH 3 PER CENT AMMONIA (V/V). WHATMAN NO. 1 FILTER PAPER

R_F values of 2 : 4-dinitrophenylhydrazones obtained from buffer-arsenite metabolism solutions		R_F values of authentic 2 : 4-dinitrophenylhydrazones of:	
	0 049	α-Ketoglutaric acid	0 049
	0·32	Pyruvic acid	0 33
Unknown keto-acid	0·50		
	0 68	Dimethylpyruvic acid	0 68
Non-acidic carbonyl compound	0·93		

When preformed felts of the same strain of *A. niger* were placed on sterile solutions of glucose (0·1 *M*) in 0·1 *M* phosphate buffer (*p*H 8 0), to which potassium arsenite had been added to give a concentration of 0·01 *M*, the same four keto-acids had again accumulated after several days at 30°. The total weight of precipitate obtained, however, on addition of 2 : 4-dinitrophenylhydrazine hydrochloride reagent to aliquots of the metabolism solution was greater than in the former experiment, in which glucose was absent from the medium.

The presence of the same unidentified keto-acid has been detected, moreover, in the culture fluid containing pyruvic and dimethylpyruvic acids obtained by allowing preformed felts of *A. niger* to li on solutions of glycerol and also of glycerol and acetate in Hida's salt solution.

We have observed that when felts of the same mould are placed on Hida's[2] salt solution to which ethyl acetoacetate (1 per cent w/v) has been added, this solution after about eight days at 30° contains pyruvic acid, dimethylpyruvic acid, α-ketoglutaric acid and again the same unidentified keto-acid encountered in the other experiments. In all instances the presence of these products was established chromatographically and was verified in repeated experiments. Work with the object of isolating the different products in the form of crystalline derivatives is now in progress in these laboratories.

The strain of *A. niger* employed in these experiments is one that gives only small yields of citric acid from glucose (10–15 per cent of the glucose utilized); and, in view of this, our results would seem to indicate that citrate accumulates in sugar cultures of those strains of *A. niger* in which the enzyme system metabolizing citric acid is either deficient or weak, and that in other strains of this mould any citric acid produced is afterwards transformed, in part at least, by way of the tricarboxylic acid cycle.

Our detection of dimethylpyruvic acid and of α-ketoglutaric acid in the mixture of products arising from both carbohydrate and ethyl acetoacetate may be an indication that the mechanisms by which the mould converts glucose to citric acid, and to the 4-carbon dicarboxylic acids common to the Szent-Györgyi systems in equilibrium and the Krebs cycle, are linked closely to those which give rise to certain acidic products and derivatives of the same which are all built on the isoprene skeleton.

During the progress of these studies, we learned from Dr. D. J. D. Hockenhull, a former colleague at Manchester, that work on parallel lines was being undertaken by Glaxo Laboratories, Ltd. This led to our consultation and an exchange of views on matters of mutual interest, and it is a pleasure to acknowledge this friendly collaboration. We desire to thank Prof. H. A. Krebs for the gift of a specimen of the 2 : 4-dinitrophenylhydrazone of α-ketoglutaric acid which we have used for purposes of comparison.

Production of Ketoglutarate by *Penicillium chrysogenum*

Krebs and Eggleston[1] have isolated ketoglutaric acid (I) during a study of arsenite-inhibited pyruvate utilization by pigeon's breast muscle. Lockwood and Stodola[2] have isolated substantial yields of the same compound from a *Pseudomonas fluorescens* fermentation of glucose. From moulds its isolation has been reported only by Uemura[3], who obtained it on deamination of glutamic acid by *Aspergillus oryzae*.

When washed, starved mycelial suspensions from *P. chrysogenum* Q176 var. *brevisterigma*[4], originally grown in submerged culture, had been shaken aerobically with lactate in presence of arsenite, substantial amounts of keto-acids could be isolated; we determined their nature after filter-paper chromatography (Cavallini *et al.*[5]), using water-saturated *sec.* butanol. Substantial yields, consisting almost exclusively of ketoglutaric acid, were frequently obtained.

In presence of 0·01 *M* sodium arsenite at *p*H 7·3, we obtained 400 mgm. of the crude 2 : 4-dinitrophenylhydrazone of ketoglutarate from 2·8 gm. potassium lactate. After crystallization from ethyl acetate, light petroleum (boiling point 40–60°) and ethanol, it melted at 217–218° (authentic phenylhydrazone, melting point 219°, and a mixture, 218–219°: C, 40·87; H, 3·23; N, 16·90 per cent; authentic phenylhydrazone required C, 40·50; H, 3·07; N, 17·18 per cent).

It was later found that, at *p*H 5·0 as opposed to the original *p*H 7·3, inhibitor was not necessary for the production of keto-acids.

From 1·0 gm. of potassium lactate we obtained 0·80 gm. of the phenylhydrazone contaminated with material having an R_F between those of the derivatives of pyruvate and dimethyl pyruvate. By chromatography on alumina a large fraction of the nearly pure phenylhydrazone, weighing about 550 mgm., was isolated; it was recrystallized from ethyl acetate – light petroleum to give a product that melted at 218–219° and did not depress the melting point of authentic 2 : 4-dinitrophenylhydrazone of ketoglutarate.

A fuller account of this work is being submitted for publication elsewhere. We are happy to acknowledge a friendly interchange of views and collaboration with Dr. T. K. Walker and his colleagues at Manchester, who have been working on parallel lines[7].

Inositol, a Major Constituent of the Seminal Vesicle Secretion of the Boar

In the course of the recent isolation of ergothioneine from boar's vesicular secretion[1], an alcohol-precipitable fraction was separated which did not contain nitrogen or sulphur; upon further purification of this fraction, crystalline material was obtained which tasted distinctly sweet, was optically inactive and non-reducing, and which gave a strongly positive Scherer reaction[2,3] characteristic of inositol. After recrystallization, first from ethanol and next from water, 18 gm. of pure meso-inositol was obtained from 1 litre of the vesicular secretion. The substance had a melting point of 225° C., and was found to contain 40·28 per cent C and 6·79 per cent H as against 40·11 per cent C and 6·66 per cent H expected theoretically; on oxidation with periodic acid[4] it showed a titration curve identical with that of pure meso-inositol. The concentration of inositol in the boar's seminal vesicle secretion exceeds considerably the amounts hitherto recorded for material of either plant or animal origin. The dry matter of 1 litre of vesicular secretion is about 150 gm., one-third of which is dialysable; of this no less than 18 gm. or 40 per cent is free inositol.

The physiological function of inositol has been mostly linked with its role as vitamin, lipotropic and growth factor[4]; its deficiency has also been reported to cause some disturbance in animal reproduction[5]. It is interesting to note that in the boar, in any event, inositol is secreted by the same accessory gland as fructose[7] and citric acid[8]; in this connexion fœtal blood may be mentioned as another example of the simultaneous occurrence of inositol and fructose[9,10]. The distribution of seminal inositol in other species, the place it occupies in sperm metabolism and its relation to the other constituents of semen are under investigation.

This study was carried out on behalf of the Agricultural Research Council. The analyses for carbon and hydrogen are by Drs. Weiler and Strauss. I am indebted for valuable help to Prof. D. Keilin, Dr. D. J. Bell and Mr. R. W. Pomeroy.

Chromatography of Adrenotropic Hormone on Ion-exchange Columns

During the past year there have been several observations which have indicated that adrenotropic hormone (ACTH), as measured by the ascorbic acid depletion test[1], might be a basic substance. Payne, Raben and Astwood[2] observed that its activity could be adsorbed on powdered cellulose from dilute acetic acid solution and eluted again by 0·1 *N* hydrochloric acid, and these experiments agreed with results from preliminary trials in this laboratory on the behaviour of adrenotropic hormone when subjected to solvent partition (some of these initial experiments were carried out in collaboration with Dr. H. G. Khorana, of the Department of Chemistry, University of Cambridge) and preparative electrophoresis. Astwood, Raben, Payne and Grady[3] have since utilized a single-step adsorption of adrenotropic hormone activity on oxycellulose (10·4 per cent COOH). We have concurrently been exploring its behaviour on columns of 'Amberlite *IRC*-50', which have previously been found to permit effective chromatographic purification of low-molecular weight basic proteins, such as ribonuclease[4] and lysozyme[5].

ACTH 'protein hormone' was prepared from pig pituitaries by the method of Fishman[6], with omission of exposure to strong ammonia. When this protein preparation (activity = approximately 1 × Armour Standard preparation *La*-1-*A*) was chromatographed on the synthetic carboxylic acid resin *IRC*-50 (*XE*-64)[4], the curve given in Fig. 1 was obtained. The results in Fig. 2 were obtained with 'crude corticotropin' (activity = 1–2 × *La*-1-*A*) prepared by the method of Astwood and his colleagues[2]. The position of the active peak on the effluent curve is a function of *p*H. The active material moves rapidly with the main proteins at *p*H 7, the degree of retardation increasing as the *p*H is reduced below 6·6.

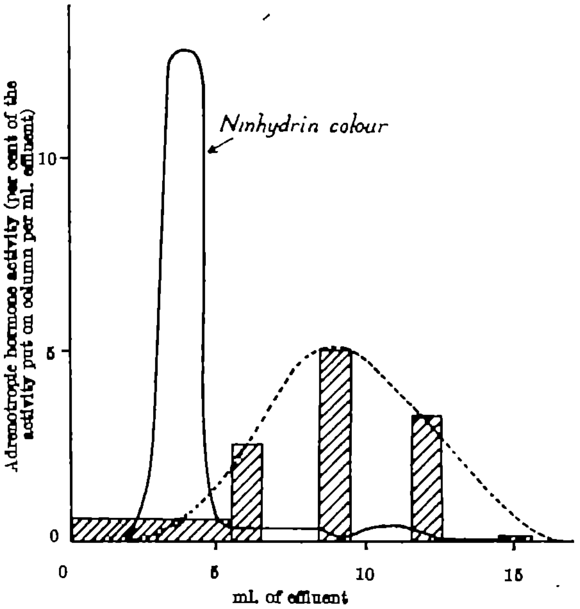

Fig. 1. Chromatography of ACTH 'protein hormone' on 'Amberlite *IRC*-50' with sodium phosphate buffer of *p*H 6·8 (0·2 *M* in phosphate). 10 mgm. of the protein was put on a 1 cm. × 10 cm. column

The results indicate that the active material in preparations of adrenotropic hormone can be satisfactorily chromatographed on ion exchange columns of fair resolving power under the mild conditions of neutral *p*H and room temperature. With the 'protein hormone', 50–100 per cent of the biological activity was recovered in fractions containing less than 5 per cent of the ninhydrin-positive[7] material. It is important to note that the major protein component

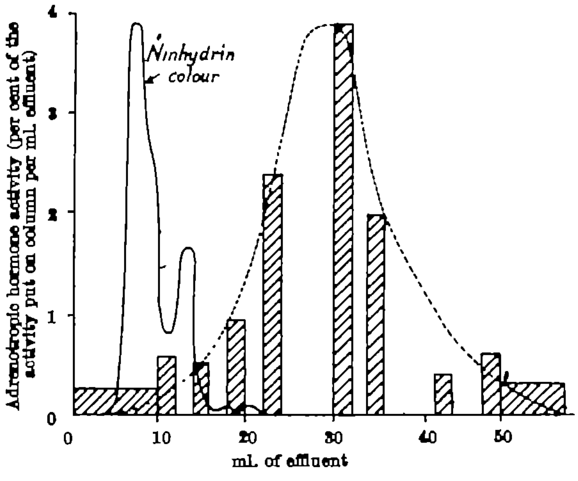

Fig. 2. Chromatography of 'crude corticotropin' (ref. 2) on 'Amberlite *IRC*-50' with sodium phosphate buffer of *p*H 6·65 (± 0·02) (0·2 *M* in phosphate). 100 mgm. of crude corticotropin was extracted with 2·6 ml. of the buffer and 1·6 ml. of the solution put on a 1 cm. × 85 cm. column

is essentially inactive. With 'crude corticotropin', 50–100 per cent of the activity was recovered in fractions which corresponded to 2–5 per cent of the starting solution on a ninhydrin colour basis. Although removal of the sodium phosphates by ion exchange to yield a salt-free powder leads to some loss of activity, we find that the active fractions contain less than 1 per cent of the weight of the starting material, and their potency may be as much as a hundred times that of the starting material. These highly active preparations are unstable in dilute solution even in acid media; but we have found that the addition of 0·2 per cent of phenol together with 0·2–0·5 per cent of the anti-oxidant thiodiglycol ($S(CH_2CH_2OH)_2$) to all solutions, including those used for dilution of samples before bioassay, eliminated the major losses.

The chromatographic results help to clarify our understanding of adrenotropic hormone. In line with the earlier observations[2,3], the evidence indicates that the ascorbic acid – depleting factor is a highly active basic substance, readily separable under non-hydrolytic conditions from the proteins which have been the major constituents of the early preparations of the hormone.

We wish to express our thanks to the Nuffield Foundation for generous support of this research, and to the Armour Laboratories, Ltd., for the gift of standardized preparations. One of us (H. B. F. D.) is grateful to the Medical Research Council of Ireland for a studentship held while much of this research was carried out.

Effect of Certain Nucleic Acid Constituents on the Growth of Some Higher Fungi

ALTHOUGH the nucleic acid purines are known to be essential growth-factors for several bacteria, they have not been found to produce any positive effect on the growth of fungi, except in four cases, namely, *Phycomyces blakesleeanus*[1], *Lenzites betulina*, *Polyporus abietinus* and *Polyporus annosus*[2]. The last two, where a strong effect of adenine was noted, have now been more thoroughly investigated.

In an earlier study[3], almost optimal growth of these two species had been obtained in a purely synthetic medium with vitamin B_1 as the only growth-factor added, and the fact that the strains responding to adenine had been in culture for fourteen and seven years, respectively, gave rise to the suspicion that their unexpected behaviour was correlated with ageing. New naturally occurring strains reacted, however, in the same way (Table 1), and the reaction seems therefore to be a physiological character of the two species, or at least a character occurring in certain wild strains.

Table 1. GROWTH OF SEVEN SPECIES OF HYMENOMYCETES IN LIQUID CULTURE WITH AND WITHOUT ADENINE

Each culture flask with 25 ml. nutrient solution M3 (see ref. 4) + 1 μgm. vitamin B_1. Average values, ± standard errors, taken from six or eight cultures. Temperature 25° C.

Species and year of isolation	Incubation time (days)	Dry weight of mycelium (mgm. per flask)	
		No further addition	1 mgm. adenine per flask
Polyporus abietinus (1937)	10	2·7 ± 0·2	4·9 ± 0·6
,, ,, ,,	15	18·7 ± 0·3	49·2 ± 5·8
,, ,, ,,	20	47·0 ± 2·9	83·3 ± 9·4
,, ,, (1951)	15	42·2 ± 2·9	60·8 ± 1·8
Polyporus annosus (1944)	15	4·9 ± 0·4	12·5 ± 0·7
,, ,, ,,	20	25·8 ± 2·5	53·7 ± 5·8
,, ,, (1951)	15	2·2 ± 0·1	3·0 ± 0·1
Mycena flavo-alba (1948)	25	1·6 ± 0	12·8 ± 0·3
Mycena rubromarginata (1948)	25	2·4 ± 0·4	13·1 ± 1·6
Mycena metata (1948)	25	15·0 ± 0·8	20·6 ± 1·3
Mycena zephirus (1948)	25	14·2 ± 1·2	21·8 ± 0·9

The effect of adenine was also studied in seventeen other species of wood- and litter-inhabiting Hymenomycetes. A strong positive response was found in some species of *Mycena*, particularly in *M. flavo-alba* and *M. rubromarginata* (Table 1), which in addition are partially tyrosine-deficient[4].

Growth-curves showed that the effect consisted mainly in a shortening of the lag-phase, the mycelial production in the control cultures catching up with the purine series at the end of the experiment (in *Polyporus abietinus* and *P. annosus* after thirty days). The lowest active concentration was found to be c. 100 μgm./litre.

In *M. rubromarginata*, all other purine derivatives tested, except adenosine, were inactive; in *M. flavo-alba*, hypoxanthine, and in the two *Polyporus* species hypoxanthine, guanine and guanosine also produced a growth-promoting effect, although it was somewhat weaker than that due to adenine.

It is suggested that these responses are due to deficiencies in the biosynthesis of purines in the fungi in question. An investigation of a greater number of wood- and litter-inhabiting fungi would probably reveal further cases of purine deficiency. A comparative biochemical study of all these cases may contribute to the picture of the biosynthesis of purines in fungi, which now is based chiefly on investigations

Table 2. EFFECT OF ADENINE AND TRYPTOPHANE ON THE GROWTH OF FOUR SPECIES OF HYMENOMYCETES

Nutrient solution, etc., as in Table 1

Species	Incubation time (days)	Dry weight of mycelium (mgm. per flask)			
		No further addition	1 mgm. adenine per flask	1 mgm. tryptophane per flask	1 mgm. adenine + 1 mgm. tryptophane per flask
Lentinus lepideus	20	57·0 ± 3·2	57·0 ± 2·2	19·9 ± 2·1	44·8 ± 3·4
,, ,,	25	100·0 ± 2·5	—	85·3 ± 5·7	105·5 ± 7·0
Trametes heteromorpha	30	26·4 ± 5·3	20·5 ± 5·2	7·5 ± 0·7	24·8 ± 5·3
Polyporus annosus	15	7·6 ± 0·6	11·8 ± 0·9	3·4 ± 0·5	9·1 ± 0·6
Pemophora fraxinea	15	14·1 ± 3·0	11·1 ± 1·3	9·3 ± 1·3	22·7 ± 2·6

of artificially produced purine-deficient mutants of Ascomycetes.

In this connexion it may be mentioned, however, that in certain circumstances a growth-promoting action can also be obtained in several species, besides those mentioned above. If the amino-acid tryptophane is included in the nutrient solution, the growth of many fungi is inhibited[5], this inhibition in several cases being totally or partially overcome by a simultaneous addition of adenine (Table 2). In *Lentinus lepideus* various concentrations of the two substances were tested. When the ratio of adenine to tryptophane was 0·3, the inhibition was released to the extent of about 50 per cent; when the ratio of these substances was greater than or equal to 1. the inhibition was removed completely. This effect, however, varied to a certain degree with time.

The real nature of this interaction is still obscure. A parallel can perhaps be found in the recent observation of Schopfer[6] that an excess of vitamin K induces a requirement for nicotinic acid (or related substances) in *Phycomyces*. Even if the mechanism of these phenomena should prove to be quite different, they indicate the possibility that an excess production of one metabolite—caused by mutation or by unusual cultural conditions—may be made apparent by the appearance of a requirement for another metabolite.

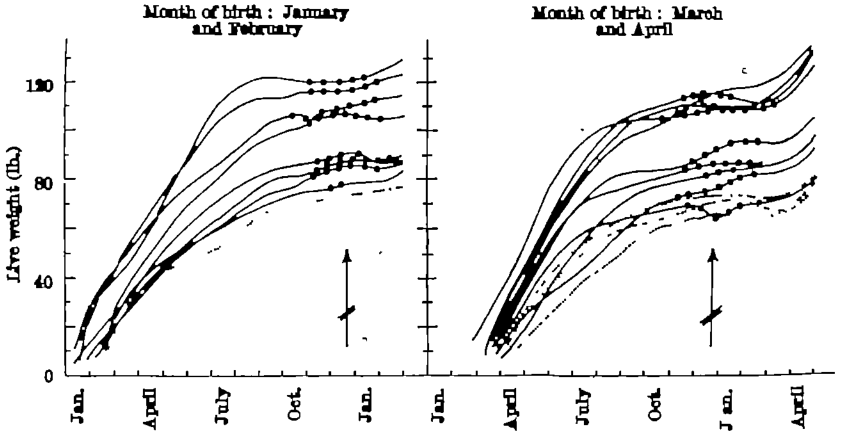
Sexual Season in Ewe Lambs

THE sexual season of ewe lambs lasts only a quarter to a third as long as that of adults[1]. In ewe lambs, sexual activity starts during November and December in Cambridge (N°)[2], while it starts during June in New Zealand (S°)[3]; and consequently the sexual season coincides with the shortest days of the year irrespective of the hemisphere. Their sexual season, which varies with the breed, is not spread evenly about the shortest day as it is with adults[4]. The onset of the sexual season in ewe lambs varies with the month of birth[2,5]; data regarding the cessation or extension of the sexual season are notably lacking.



—●—, Œstrus; —○—, silent heat; . . . . , ewe lambs did not show heats. Shortest day marked by arrow

Œstrous performance in relation to growth-rates in Suffolk ewe lambs

Two groups of grade Suffolk ewe lambs were available, one born in January and February and the other born in March and April. They were weighed regularly from birth and were put after weaning with active vasectomized ram lambs for one year. The ram lambs were ochred, and observations for œstrus were made daily. Results concerning the sexual season of both groups are shown in the accompanying table.

The proportion of ewe lambs which did not show any œstrus during the first autumn was 11 per cent and 20 per cent in early- and late-born lambs respectively. The average date of onset and cessation of the sexual season was 3½ weeks earlier in the early-born ewe lambs than that of the late-born. The average duration of the sexual season was 66 days in both groups. Early-born lambs experienced on an average more heat periods per ewe per season than late-born ones. Silent heat occurred more frequently in the late-born animals, and the number of silent heats expressed to the possible total number of heats was 7 per cent and 14 per cent in early- and late-ewe lambs respectively.

The live weight at the onset of the sexual season (first heat) ranged from 66 to 121 lb. with no significant difference between the two groups. Meanwhile, ewe lambs with retarded growth (both early- and late-born) either did not show œstrus in their first autumn or experienced few œstrous cycles (see diagram). In both groups ewe lambs with higher growth-rates showed more œstrous cycles and fewer silent heats. The growth was checked during the sexual season, this being due not to their attaining sexual maturity but to seasonal variation in the nutritive value of pasture.

It is concluded that œstrous performance in ewe lambs is controlled by a complex factor: the daylight environment and the growth-rate. Maximum sexual activity coincides with the shortest days, presumably the peak period of the activity of the

Month of birth	January and February		March and April	
	Range	Mean ± S.E.	Range	Mean ± S.E.
Date of onset	Oct. 15–Nov. 23	311 ± 6·2*	Oct. 27–Dec. 18	333 ± 5·1*
Date of cessation	Dec. 10–Feb. 6	12 ± 5·8*	Dec. 9–Mar. 12	34 ± 6·3*
No. of heats per ewe lamb per season	0–7	4·2 ± 0·4	0–8	3·6 ± 0·6
No. of silent heats per ewe lamb per season	0–2	0·4 ± 0·1	0–3	0·8 ± 0·2

* The period elapsed from December 31.

pituitary gland. Once the sexual season has started, œstrus is experienced at regular intervals (cycle-length 16·51 ± 0·18 days) provided that the daylight environment is favourable. Ewe lambs which show their first œstrus after the shortest day have consequently the shortest sexual season. It is suggested that, for the manifestation of œstrus in ewe lambs, certain thresholds of live weight, in the same way as the hormonal thresholds, are required. In the Suffolk (see diagram) the thresholds which play a part during the favourable daylight environment are classified as follows: (I) above 100 lb., high œstrous performance (maximum); (II) 75–100 lb., heat periods interspersed by silent heats; (III) less than 75 lb., low œstrous activity or no activity at all (minimum).

This work was financed by the Agricultural Research Council and was carried out in the Animal Research Station, Cambridge, during study leave from Fouad I University, Egypt. Thanks are due to Dr. John Hammond for continuous advice and encouragement.

A New Platyctenid Ctenophore from Jamaica

Platyctenid Ctenophores have now been discovered along the shores of Jamaica. This is the first record of these interesting forms from the West Indies, although related forms have been recorded from the coast of Florida[1].

In May 1950 five transparent, colourless Platyctenids were noticed adhering to the sides of a tank containing the black solitary tunicate, *Ascidia nigra* Savigny, which had been collected from mangroves on the previous day. Similar Ctenophores were afterwards found in the natural habitat actually creeping on these ascidians, presumably as commensals.

In the following July, more than a hundred specimens were found on the cœnosarcs of Dynamenid hydroids from the same locality. These forms were pale pink or pale green in colour, but appeared to have the same basic structure. All these specimens closely resembled the genus *Cœloplana*, but also showed certain extremely interesting and well-marked features which are indicative of at least a new species and possibly of a new genus. Two of these features may be mentioned here, namely, (1) the presence of oral grooves with well-marked edges which curve round to end on the aboral surface in continuity with the openings of the tentacular sheaths, and (2) the presence of marked oral lappets which become produced laterally as the edges of the oral grooves.

A full description of the distinctive characteristics, habits and microscopical anatomy of these new Platyctenids is in the course of preparation and will be published shortly.

History of Science and Technology in India and South-East Asia

Dr. Joseph Needham has very ably reviewed in *Nature* of July 14, p. 64, the series of papers that were read at the symposium on the "History of Sciences in South Asia", and has drawn some pertinent conclusions therefrom. He has, however, not been able to gauge the spirit in which the symposium was held, or expatiate on the new lights that were thrown on the subject. He has, on the other hand, omitted to mention certain salient facts about the organization of the symposium, and the review gives by omission the erroneous impression that it was solely the work of the Unesco Science Co-operation Office for South Asia. As chairman of the symposium, and now president of the National Institute of Sciences of India, I wish to put on record the part played by the National Institute in the symposium.

The idea of holding a symposium on the history of sciences in South Asia was first mooted by Dr. D. S. Kothari, one of the secretaries of the Institute, which received the support and co-operation of the Unesco Science Co-operation Office in Delhi. Accordingly, the symposium was held under the auspices of the National Institute of Sciences of India, in collaboration with the Unesco Science Co-operation Office, in Delhi, during November 5–7, 1950. Facilities for holding the meetings and accommodation for the visiting delegates were generously provided by the University of Delhi. A number of scientific men, historians and oriental scholars from India and abroad attended the symposium and took part in its deliberations. From the mimeographed copies of the papers that had been circulated in advance, it was clear at the very outset that considerable controversy was bound to arise about the dating of the most important texts, and to overcome this difficulty a Chronology Committee, consisting of historians and scientific men, was appointed at the business meeting prior to the symposium. This Committee felt that it was very difficult to ascertain with accuracy the dates of Indian literary works supposed to belong to the pre-Christian era. But after discussing the matter at length, it recommended that the chronological table given below might be taken as a working hypothesis in connexion with the discussion of papers of the symposium. The table is based on the standard work "History of Indian Literature" by Winternitz.

The authors of papers were then asked to revise their papers according to the dates given in the table for various texts. Owing to very divergent views, however, it was not intended to have all the papers published in full. In reviewing that motley of papers, which were not authorized for publication, and stating that mimeographed copies are available at the Unesco Science Co-operation Office in Delhi, Dr. Needham has unwittingly done an

CHRONOLOGICAL TABLE

Age of the Rigveda	2000 B.C. to 1500 B.C.
Age of Samhitas and Brahmanas	1500 B.C. to 800 B.C.
Age of old Upanishads	900 B.C. to 599 B.C.
Charaka	A.D. 100
Charaka Samhita—kernel of	A.D. 100, but enlarged in later times
Susruta Samhita	A.D. 200 to A.D. 500
Vedanga Jyotisha—present text	500 B.C.
Sulbha Sutras	500 B.C. and later
Dharmasutra	600 B.C. to 200 B.C.
Mahabharata Manusmriti Ramayana	200 B.C. to A.D. 200

injustice to the National Institute of Sciences of India and to the organizers of the symposium. A summary of the proceedings of the symposium is in preparation for publication by the Institute.

The great difficulty with which a scientific worker is faced in a study of the history of science in India lies in the fact that the available ancient materials and documents are written either in Pali or Sanskrit languages, with which he is generally not familiar. He has, therefore, to depend upon oriental scholars for interpretations and commentaries of texts for dating ancient literature. There is, however, a lack of scientific knowledge among historians and orientalists, and this makes it difficult for them to appreciate and evaluate the scientific thought of ancient India. In the case of fixing the dates of various texts, there is no unanimity among historians. Hence the participants in the symposium came to a decision that in future scientific workers dealing with the history of science in India should give original texts, and the names of the source books for reference by the historians and orientalists.

The scientific men in India, as elsewhere, are well qualified by experience to sift and analyse their data before arriving at any definite conclusions. For example, my own contributions on fishery legislation, based on "Arthasastra" and the Asoka Pillar Edict, were read by many eminent oriental scholars, who have expressed agreement with the interpretations suggested by me. Nevertheless, whenever a 'conservative view on any matter is challenged, adverse comments are likely to result. It is therefore the duty of the scientific workers to make a correct approach to and appraisal of the scientific knowledge of ancient India, notwithstanding prejudices that may exist already about the history of India's cultural heritage and scientific thought. "The study of the history of science in India," as remarked by Dr. Needham, "remains enthralling."

S. L. HORA
(President)

National Institute of Sciences of India,
Mathura Road,
New Delhi 1.
Oct. 5.

I HAVE read Dr. Hora's communication with interest and sympathy. It was a great disappointment to me that I was not able to accept the invitation to participate personally in the Conference, but after the publication of my review in *Nature* I became aware of the work of the Chronology Committee through the report published by Dr. Hora at the conclusion of Dr. Wolsky's review in *Archives Internationales d'Histoire des Sciences*, 4, 579 (1951), and I was pleased to find so much concordance of view. My chief object in acceding to the request of the Editors of *Nature* that I should review the conference papers sent to them, which neither the Editors nor I knew were in any sense unauthorized, was to encourage interest in the history of Indian contributions to science.

JOSEPH NEEDHAM

Physics of Social Equilibrium

IN his review of my paper of this title, read to Section A (Physics) of the British Association at Edinburgh, Prof. T. S. Simey raises certain criticisms which, I think, are mainly due to some misunderstandings. As my paper has so far not appeared in print, I wish to set out briefly the main points of my argument.

In theoretical physics use is made of simplified models for representing groups of phenomena. The limitations of such models are clearly understood, and their purpose is to facilitate the understanding of observed facts and to provide a heuristic principle for the discovery of new relationships. It seems quite legitimate to use physical models for the representation of non-physical phenomena, for example, of social phenomena, for this express purpose.

I pointed out the inadequacy of two such models which are frequently used. The first represents a human society by a mechanical system which is subject to the classical laws of dynamics, like a mechanical machine. The second model regards such a society as a 'loose statistical assembly' with practically no interaction between its members, like the assemblies of particles which in the kinetic theory of gases represent a rarefied material substance, and assumes that the social phenomena are ruled by the statistical laws of games of chance which can be derived from the probability calculus under the condition of mutual independence of the individual events.

I suggested the use of a more adequate model incorporating both the causal and the chance aspects of the phenomena involved, namely, a so-called 'close assembly' of particles with strong mutual interaction, like a liquid or a solid. The physical behaviour of such a model is governed by the laws of statistical mechanics, and its characteristic feature is that the individual fate of a member of the assembly is neither strictly determined, as in the first of the rejected models, nor strictly undetermined, as in the second one; the probabilities for the various possible events in the future are not fixed, but depend on the present state of the whole assembly. This gives rise to the so-called 'co-operative phenomena' in physics which are characteristic of dense material substances. I discussed a few examples of such co-operative phenomena, like ferromagnetism, phase transitions in crystals and strength of solids, and directed attention to the striking similarity between these and certain social phenomena. I therefore pleaded for the use of this sort of model as a heuristic principle for the guiding and shaping of human societies.

I thought I had made it perfectly clear that I neither intended to get to "an understanding of the very purpose of human life", nor to discredit the application of statistical methods in sociology. I only criticized some inadequate physical models of society and proposed a less inadequate one the very essence of which is its statistical nature. It was the indiscriminate application of the calculus of probability, as used in the statistics of games of chance, which I argued against, and I cannot see that by doing so I have "over-stated my case".

The analogy I drew between the behaviour of human societies and close physical assemblies, like crystals (not, as Prof. Simey writes, "communities of crystals"), was meant solely to demonstrate that the co-operative phenomena working in both these cases are of a similar nature. For the fundamental assumption made is only that a strong 'interaction' of some sort or another is taking place; whether this interaction is of a conscious or an unconscious nature is not essential for the characteristic features of a co-operative phenomenon.

If the proposed model is indeed a reasonable representation of human society, various measures, introduced in the past for strengthening social communities, appear to be founded on unsound principles and are bound to produce the opposite effect. It was in this connexion that I mentioned the political stability of the United Kingdom; but I never intended more than to make a very modest contribution towards the understanding of this stability.

I quite agree with Prof. Simey that the value of statistical mechanics for the social sciences will have to be established by extensive experiments, although I am not sure whether such communities as a factory working group or a housing estate are sufficiently large assemblies to justify the proper use of the theory of co-operative phenomena. I should be quite satisfied if my paper induces social scientists to undertake such experiments.

R. FÜRTH

Birkbeck College,
University of London.

I AM much reassured by what Dr. Fürth has said, since he has made it clear that his intention was to object to the 'indiscriminate' application of statistical methods to social problems, rather than to suggest that the use of those methods was necessarily misleading. I do not, in fact, see much evidence of misuse of statistics in this way by my academic colleagues; but I agree that less-sophisticated people are often led into errors of this kind, and it is useful to point it out.

Dr. Fürth has performed a valuable service in directing attention to a mathematical 'model' which has not so far been made use of in the interpretation of social phenomena. But I can only reassert my view that it would be a retrograde step if we were to allow ourselves to argue by analogy, and to conclude as a result that "various methods, introduced in the past for strengthening social communities, appear to be founded on unsound principles and are bound to produce the contrary effect".

The value of these suggestions needs to be tested by experiment and observation; but the possibility of doing so appears to be somewhat remote when doubt is cast on the value of using the working population of a factory or the inhabitants of a housing estate as the material of an experiment, on the ground that their numbers are not sufficiently large. Dr. Fürth must tell us more about the minimum numbers which would be significant for this purpose, and throw more light on the methods which might be used to achieve it.

University of Liverpool.

Non-adaptive or Neutral Characters in Evolution

SEWALL WRIGHT[1] has shown that, given certain ecological conditions, drift will occur and produce an apparently random pattern of variation. Some authors have thereupon employed genetic drift, in the same way as adaptive neutrality was formerly employed, to explain every example of variation which in their opinion is random. This procedure is wrong. They have not proved drift to be acting, but have failed to prove that selection is acting, and have invoked drift to cover the failure. An explanation which depends for its success on the failure of the investigator cannot be regarded as satisfactory.

I do not claim, as Carter[2] states, that we must now accept that there is no evolution of non-adaptive—or neutral—characters in Nature. Such a claim would be as difficult to maintain as the claim that genetic drift is common and important. Probably drift does occur, to some extent. But every example of it so far adduced either rests on the logical fallacy pointed out above and in a previous communication[3], or remains uninvestigated, or has been disproved on further investigation. The more the interactions between genes and their environments are studied, the less likely does it become that genes controlling definite characters can possess, except perhaps for very short periods, the very low selective coefficients necessary for extensive drift.

It seems, therefore, that in view of the complexity of living systems and their environments, the investigator should be cautious and not use drift or selective neutrality as an explanation for all unanalysed cases. As Carter[2] points out, what is wanted is more investigation; but it is doubtful whether any example of variation in Nature can be so completely analysed that, after selective effects have been estimated, the residual variation can be ascribed with confidence to genetic drift. There is always the possibility, indeed the likelihood, that the analysis of selective effects was not complete.

A. J. CAIN

Department of Zoology and
Comparative Anatomy,
University of Oxford.

[1] Wright, S., *Genetics*, 16, 97 (1931); "The New Systematics", 161 (London, 1940); *Evolution*, 2, 279 (1948).

[2] Carter, G. S., *Nature*, 168, 700 (1951).

[3] Cain, A. J., *Nature*, 168, 424 (1951).

I AM glad that Cain admits that genetic drift may be a real factor in evolution, even though he may not be willing to admit that its effect is significant. Since I have not wished to express an opinion on the relative importance of selection and drift, it seems that the only point at issue between us is that I do not accept the present evidence as being so strongly against drift that we should not, when dealing with some types of evolutionary change—especially trivial changes in micro-evolution—regard it and selection as equally possible explanations when neither is proved. If we do so regard them, it seems as much a fallacy to assume selection alone where there is no disproof of drift, as to assume drift wherever there is no proof of selection. If in any case analysis of selective effects is incomplete, this fact cannot be used as evidence against drift as the efficient cause.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, December 17

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. E. C. Cherry : "What Practical Benefits can Communication Engineers expect from the Modern Information Theory ?"

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Rt. Hon. the Earl of Verulam, Mr. J. Houston Angus and Mr. Stephen Chaplin : "Geography of Power".

Tuesday, December 18

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Dr. D. L. Gunn : "The Red Locust".

Institute of Fuel (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. J. W. R. Rayner : "Gasification by the Moving-Burden Technique".*

Tuesday, December 18—Wednesday, December 19

Association of University Teachers (in the Eugenics Theatre, University College, Gower Street, London, W.C.1).

Physical Society (in the Physics Department, University College, Southampton).—Autumn Provincial Meeting.

Tuesday, December 18

At 2 p.m.—1st Session. "Optics of Metals".

Wednesday, December 19

At 9.30 a.m.—2nd Session : "Thermal Properties and Growth of Crystals", at 2 p.m.—3rd Session : "Complex Spectra and Nuclear Structure".

Wednesday, December 19

Society of Chemical Industry, London Section (joint meeting with the London and South-Eastern Counties Section of the Royal Institute of Chemistry, at the Waldorf Hotel, Aldwych, London, W.C.2), at 4 p.m.—Symposium on "Radio-chemistry" (Speakers. Sir John Cockcroft, F.R.S., Dr. J. E. Johnson and Mr. J. Smith).

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers, Supply Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. W. R. Stoker and Mr. C. N. Thompson : "Inhibited Transformer Oil" ; Mr. P. W. L. Gosling and Mr. L. H. Welch : "The Stability of Oil in Transformers".

Manchester Literary and Philosophical Society, Social Philosophy Section (at the Portico Library, Mosley Street, Manchester), at 5.30 p.m.—Lady Simon of Wythenshawe : "Leadership—Can We Educate for It ?"

Royal Microscopical Society (in the Department of Human Anatomy, Oxford), at 5.30 p.m.—Dr. R. Barer : "A Vector Theory of Phase-Contrast and Interference-Contrast".

Thursday, December 20

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. H. D. Ursell : "Prime Ends".

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Mr. H. G. Broadbent and Mr. W. T. Kirkby : "Control Surface Flutter".

British Institute of Radiology (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 8 p.m.—Contributions on "The Diagnostic Use of P32 in Neurosurgery" (Speakers : Mr. T. P. Morley and Dr. C. W. Gilbert).

Friday, December 21

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Lieut.-Comdr. P. G. Satow : "Meteorology and Navigation".

British Institute of Radiology (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 6.30 p.m.—Dr. W. K. Sinclair : "The Use of P32 incorporated in a Plastic for Superficial Beta Therapy" ; Mr. H. F. Freundlich : "The Use of Fission Products in Surface Applicators".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned :

Senior Lecturer in Physics at the Frontier College for Women, Peshawar—The High Commissioner for Pakistan, 35 Lowndes Square, London, S.W.1 (December 20).

Principal Biochemist in the Clinical Laboratories—The House Governor, London Hospital, Whitechapel, London, E.1 (December 21).

Biochemist for full-time research on fundamental problems related to the nervous system, at the Neuro-Psychiatric Research Centre, Whitchurch Hospital—The Secretary, Welsh Regional Hospital Board, Temple of Peace and Health, Cathays Park, Cardiff (December 22).

Junior Chemists (with Inter.B.Sc., or equivalent) in the Central Laboratory, Chiswick—The Staff Officer (F/EV/197), London Transport, 55 Broadway, London, S.W.1 (December 22).

Principal of the Technical Institute—The Director of Education, Town Hall, Wallasey (December 22).

Scientist, Grade I, or Senior Scientist (with high academic scientific qualifications ; sound all-round knowledge of fuel technology and some research experience are desirable) as Chief Coal Survey Officer in the Scottish Division—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/403 (December 22).

Scientist, Grade II (with an honours degree in science, or the equivalent, and several years industrial experience) in the No. 2 (Wigan) Area Laboratory at Ince Moss Colliery, Wigan ; a Scientist, Grade II (with an honours degree in science, or the equivalent, and several years industrial experience) in the No. 4 (Burnley) Area Laboratory at Altham Coke Works, Altham, Accrington ; and a Scientist, Grade III (graduate with a first- or second-class honours degree in chemistry) at the Central Laboratory, Shade House, Swinton—The Divisional Establishment Officer, National Coal Board, North-Western Division, 40 Portland Street, Manchester 1 (December 22).

Assistant (Grade A) in Chemistry, to teach organic or inorganic chemistry to an advanced level, and general chemistry to intermediate level—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex.

Assistant Executive Engineer in the Public Works Department, Sarawak—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27322/113.

Chemist (with some experience in research) for training in methods of dyeing research—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

Chemists and Metallurgists (Scientific Officer grade) at a Ministry of Supply research establishment in Berkshire : Physical Metallurgist (Ref. F.886/51A) with sound knowledge of modern metallurgical theory ; experience in metallography or in the determination of thermal and physical properties essential, and a Physical or Inorganic Chemist (Ref. F. 887/51A) preferably with some experience of radioactive chemistry—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

Curator (with an honours degree in archæology with some anthropological training) in the Department of Museums, Malaya—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27410/1/51. Appts.

Electronic Engineer or Physicist by the Division of Atomic Energy (Production), to take charge of a group concerned with the maintenance and modification of electronic instruments at Windscale Works, Sellafield, Cumberland—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting Ref. 279

Graduate Assistant in the Biochemical Department—The Secretary, Hospital Management Committee, Dudley Road Hospital, Birmingham 18.

Head of the Department of Chemical Technology, Indian Institute of Science, Bangalore—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting A.12/1/31 B.

Health Physics and Safety Group Manager (with either an honours degree in physics or chemistry, associateship of the R.I.C. or the Institute of Physics, or equivalent qualifications) at Windscale Works, Sellafield, Cumberland—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting No. 269.

Lecturer (medically qualified, with some experience of physiological teaching and research) in Physiology—Prof. D. S. Torrens, School of Physic, Trinity College, Dublin.

Lecturer in Mechanical Engineering, to teach applied mechanics, strength and properties of materials, and some thermodynamics—The Principal, Technical College, Darnley Road, Gravesend, Kent.

Lecturer in Physiology and Pharmacology—The Registrar, College of Technology, Bristol 1.

Lecturer in Rubber Chemistry—The Clerk, National College of Rubber Technology, Northern Polytechnic, Holloway, London, N.7.

Officer-in-Charge of Camden Park Experimental Station (Agricultural), Windward Islands—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting *Nature* and M.23443.G.

Physicist (with electronic experience) for basic research on ultrasonics—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

Principal Scientific Officer—Physicist (Ref. A. 367/51A) to work on the improvement of existing techniques and investigation of new methods of photographic recording of experiments, including the use of long-focus lenses, and of colour photography ; and a Senior Scientific Officer—Electrical Engineer or Physicist (Ref. A.368/51A) for experimental work in the development of magnetic recorders and associated electronic circuits, in the Instrumentation Department of the Royal Aircraft Establishment, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting the appropriate Ref. No.

Research Assistants (with relevant academic qualification, and practical experience in either mechanical engineering design or research, or in electronics and instrumentation) for work covering a wide field of hydraulic engineering—The Director, British Hydromechanics Research Association, Harlow, Essex.

Science Graduates : (*a*) a Physical Chemist to develop methods of test in the field of adhesives, and (*b*) a Chemist for laboratory dealing with day-to-day production problems arising in the industry—The Printing, Packaging and Allied Trades Research Association, Patra House, Randalls Road, Leatherhead, Surrey.

Senior Scientific Officer or Scientific Officer (with a first- or second-class honours degree in chemistry, metallurgy or physics, or equivalent qualification, at least three years' post-graduate research experience, and a good knowledge of German or Russian) in the Information Section at the Atomic Energy Research Establishment, Harwell—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting F.897/51A.

the vitality of free institutions and on the strengthening and fostering of all that makes for positive achievement.

What matters is that the lessons to be learnt from the experience in the United States described so vividly by Mr. Barth should be applied to prevent like mistakes in Great Britain and elsewhere. The recent episode of the withdrawal of the passport of Dr. E. H. S. Burhop, a lecturer in the University of London, suggests that necessary regulations in Britain are neither always framed with imagination and understanding of the real issues nor invariably interpreted with common sense and administered with courtesy. The case was parallel with the obtuseness to human issues which is one of the worst features of American loyalty investigations. There may well be room, as Dr. Burhop reasonably suggested, for some further investigation of the question of travel rights, and the bearing of such rights on scientific work might engage the attention of the Society for Freedom in Science.

Too great caution cannot be observed in regard to any such infringement of academic freedom or of the civil liberties of scientific workers. Recently some attention has been directed to a position which has developed in Australia, apparently in consequence of a similar dependence upon the State or upon private benefactors for support of the universities to that of American colleges and universities noted by Mr. Barth. The Vice-Chancellor of the University of Adelaide, Dr. A. P. Rowe, has pointed out that the statute barring professors (and only professors) from becoming members of Parliament or members of political associations is as old as the University itself; knowledge of its existence came as a surprise to him and most of his colleagues, and it appears to be in desuetude. The Registrar of the University of Western Australia has stated that a corresponding clause in that University's general regulations, which applied also to lecturers, was dropped last year. Dr. Rowe himself believes that the Council of the University of Adelaide would be willing to remove the statute in question if any feeling on the matter existed among the staff.

Adelaide and Melbourne are the only two out of Australia's eight universities whose statutes include such a clause, although the University of Sydney requires a professor to resign on being elected to Parliament, and a clause requiring resignation on election to Parliament is being included in the contracts of all members of its academic staff by the new Australian National University at Canberra. The statute in the constitution of the University of Melbourne was enacted in 1859 in the face of vigorous opposition by the professorial staff, and the clause was presumably copied into the statutes of the University of Adelaide when that University was founded in 1874. The matter was brought to notice by Prof. J. B. Cragg's recent withdrawal of his acceptance of his appointment to the chair of zoology at Adelaide. That Prof. Cragg is right in holding this statute to be a serious infringement of the rights of the individual is sufficiently demonstrated by the reported statement of the Vice-Chancellor of the University of Melbourne, that the restriction is necessary for a university largely dependent on the State, and that for an independent university it would be entirely different. It is not suggested that the clause has hitherto been administered illiberally, and Prof. Cragg was prepared to state that he would resign his professorship if elected to Parliament. Nevertheless, in unscrupulous hands the restraint, particularly against membership of a political association, could be used to do much damage to academic freedom; and misgivings regarding operation of the clause will be encouraged by the disclosure that the Council of the University of Melbourne is considering new rules to control political discussion.

This is, of course, primarily an Australian matter and has already provoked outspoken comment in the *Melbourne Argus* and protests by students. It is well, however, that it should be known that there is no sympathy in Great Britain for such inroads into academic freedom. As the Vice-Chancellor of the University of Melbourne has revealed, what is involved is a general attitude of mind, and it is against this rather than one particular statute that Prof. Cragg made his stand. It is wrong to deny to a professor the ordinary rights of a citizen, and university authorities betray the traditions of scholarship when they fail to recognize the differences between a professor pronouncing *ex cathedra* on his own subject and the same professor deciding to support one political party rather than another outside the walls of his university.

Beyond this, it is plain that some politicians and business men in Australia are attempting to enforce orthodoxy and eliminate thoughts they regard as dangerous by withholding university funds. No true university can tolerate such interference without losing its soul. It is to be hoped that university teachers in Australia will show something of the turbulence of the old medieval universities when academic privileges and rights were invaded. If they do, they can be assured of the firm support of their colleagues elsewhere in the Commonwealth; scientific men and technologists, who to-day are rightly held as particularly responsible for maintaining the freedom of the studium or campus against outside interference, have already shown by their concern over the new status of the Australian Commonwealth Organization for Scientific and Industrial Research an appreciation of the importance for full freedom for scientific advance.

A CLASSIC IN PHYSICS REVISED

A History of the Theories of Aether and Electricity
The Classical Theories. By Sir Edmund Whittaker. Revised and enlarged edition. Pp. xiv+434. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1951.) 32s. 6d. net.

THIS is a revised edition of the well-known book published in 1910 under the title "A History of the Theories of Æther and Electricity from the Age of Descartes to the Close of the Nineteenth Century". The only reason the earlier book is not even better known to the present generation of scientific workers than it is, is that it has been out of print for so many years. Indeed, many of the present generation who recognize its author as one of the very foremost of living mathematicians and almost certainly the most versatile, and also as one who in recent years has earned an additional reputation as an authority upon the philosophy of physical science, may scarcely realize that he had so long ago established himself also as the leading historian of the theories here considered.

These are the theories that, historically, led to the development of relativity and quantum theory during the present century. It has been no secret that Sir Edmund Whittaker has for many years contemplated not only a revision of his earlier book but also a second volume dealing with these subsequent developments. His retirement from the chair at Edinburgh and the consequent leisure required for this formidable undertaking were delayed by the Second World War. Also, most will appreciate that the 'leisure' of retirement in post-war conditions is far from being of the sort to which he must have looked forward. Rarely can a self-imposed obligation have been more resolutely pursued and eventually so faithfully fulfilled. It is assuredly a very rare event for the author of a major work himself to prepare a revision forty-one years after its original publication.

Sir Edmund states, "The volume of 1910 has been to a considerable extent re-written, with the incorporation of much additional material". The re-writing is most extensive in Chapter 1, in Chapter 12 on "Classical Radiation-Theory", which is entirely new, and in Chapter 13, which corresponds to the original Chapter 12. This last now includes, for example, an account of Whittaker's own demonstration in 1904 that a general electromagnetic field may be described by two scalar-potentials instead of a scalar- and a vector-potential, and a fuller account than before of the Zeeman effect, while it omits the previously given introduction to special relativity, which is now naturally deferred to the second volume. Elsewhere, the text of the earlier book is largely preserved, though with the insertion of fresh paragraphs and footnotes. The fact that, besides mentioning other works that have appeared since 1910, these contain many new references to original sources—thus considerably lengthening the already awe-inspiring earlier "Index of Authors Cited"—demonstrates the thoroughness with which Sir Edmund has reviewed all that he had previously written.

As is very well known, it was not until the work of Maxwell and his immediate successors in the second half of the nineteenth century that the electromagnetic nature of light came to be established. But if, anticipating this development, the theory of radiation is included, the history of the theories of æther and electricity can be given in a coherent and adequately self-contained fashion. This is what Sir Edmund does. It is, of course, the story of fundamental physical science, and it could easily expand itself into the whole history of physical science. But he is brilliantly successful in keeping the emphasis upon his main themes, while at the same time making the reader aware of important concurrent developments bearing upon them or affected by them.

Descartes "was the first to bring the æther into science", and the book effectively begins with the exposition of his ideas and then, in the first chapter, reviews the theory of the æther up to and including Newton's concepts and his work on light. The next two chapters trace the history of electricity and magnetism up to Green's introduction of the electrostatic and magnetostatic potentials and to Ohm's work on electric currents. Then the history of the æther is taken up again in a chapter on the period from Bradley to Fresnel, and another on theories of the æther as an elastic solid. The history of electricity and magnetism is resumed in a chapter devoted principally to the discoveries of Faraday, followed by three (with one on "Models of the Æther" interposed) mainly about the mathematical developments leading up to the work of Maxwell, about that work itself, and about the work of his followers. The experimental work after Faraday up to Thomson's discovery of the electron is then described. Chapter 12, already mentioned, is effectively a description of the empirical work on spectral series and the empirical and theoretical work on black-body radiation that later led to the discovery of quantum phenomena. The final chapter centres round the Lorentz electron-theory of optical phenomena and of electric and thermal conduction.

Besides giving a clear statement of the experimental discoveries, upon which the theories were founded, and a most penetrating account of the physical concepts employed, Sir Edmund in his book actually re-derives in outline the mathematics of these theories. Thereby he not only provides a much more precise account than would otherwise have been possible, but also he is able to display the general forward march of the achievements far more clearly and to demonstrate the relations between various contributions far more concisely. In this way, too, he succeeds in showing the importance of work such as Weber's, which played an essential part in the historical development without itself remaining as a permanent feature of accepted theory.

Sir Edmund Whittaker has recorded a monumental amount of scholarly information. But what he has above all succeeded in doing, possibly more than any other historian of science, is to impart a comprehensive and authentic impression of that wherein the great pioneers were truly great. He enables us to see their work, with its lack of precedents, against the background of strangely assorted experimental data and of contemporary conflicting general physical concepts, and to see how they yet contributed each his share to what we are bound to recognize as permanent progress. No better factual account exists to show how hardly won that progress has been.

W. H. McCrea

GENETICS AND ANTHROPOLOGY

Genetics and the Races of Man

An Introduction to Modern Physical Anthropology. By Prof. William C. Boyd. Pp. xvii+453. (Oxford: Blackwell Scientific Publications, Ltd., 1950.) 30s. net.

In the present state of development of physical anthropology, this book must be accounted of particular interest. It is not the guide to the whole field of modern physical anthropology which the subtitle may suggest; nevertheless, it provides a thoroughgoing introduction to that large section of the subject which at the present time is undergoing rapid progress, that is to say, the analysis, through genetics, of human diversification, evolutionary and racial. The book fully justifies Prof. W. C. Boyd in his claim that human genetics has advanced to the point where it has rendered totally inadequate the hitherto accepted classification by superficial phenotypic or 'morphological' criteria, an approach which for the most part leaves unspecifiable the degree of innate relationship between human groups.

This exposition by Prof. Boyd will do much to ensure henceforth the primacy in racial anthropology of genetic method. For this approach provides, through the enumeration of the frequency of identifiable genes in different populations, an entirely objective assessment of genetic relationship. Moreover, it allows some insight into the likely mechanisms at work in human differentiation, taking into account the operation of such factors as population size, systems of mating, isolation and selection. Thus the origins of modern racial groups, the rate and extent of admixture, and the significance of 'clineal' and other modes of geographical distribution can all be understood as dynamic and historical processes. By the older method, despite statistical refinement, the analysis of these phenomena cannot rise above the descriptive level. The basis of these new advances lies, of course, in the comparatively recent discovery of new blood-group systems, the elucidation of their hereditary mechanism, and the application of the evolutionary principles formulated by Haldane, Fisher, Wright and Huxley. All these topics, both in their genetic and mathematical aspects, are dealt with satisfyingly by Prof. Boyd. Some readers, however, may find the chapter on the elements of genetics too skimped; there is, for example, insufficient discussion of multiple factor inheritance.

Prof. Boyd has found it possible to demarcate six human groups as racial or sub-specific entities on a strictly genetic basis without reference to any of the older criteria such as hair shape or skin colour. This alone shows that a complete re-orientation in physical anthropology has been effected. But is Prof. Boyd doing the subject a service in the castigation he metes out to some of the older workers who have been somewhat slow to appreciate that their concepts are becoming outmoded ? Much of his criticism seems unnecessary in order to establish the scientific superiority of the genetic approach. The new reader in this introduction is likely to obtain a distorted impression of past work in racial physical anthropology. He will certainly fail to appreciate, for example, the great contribution represented by the statistical biometry of the Pearson School, even if one admits the weaknesses to which Prof. Boyd directs attention. It is only fair, also, to insist that in the past reasonably good use was made of the only information which human genetics could offer until quite recently, namely, that derived from the *ABO* blood-group system. Prof. Boyd does not really make it plain enough that, while data using identifiable genes such as the blood-group genes have become a *sine qua non* of anthropological field-work, there are many good reasons why information on other characters of imperfectly known or even unknown genetic constitution should continue to be collected. The hereditary basis of some of these is bound in time to be clarified, as has happened recently to some extent in the case of a polygenetic feature such as body build. In any event there are many other legitimate uses in anthropology to which such data can be put.

This lack of perspective is a blemish in an otherwise excellent book. It invites the further comment that Prof. Boyd, like some of those he severely criticizes, does not quite avoid a tendency which should be guarded against in physical anthropology—the undue preoccupation with racial classification as such, which carries with it the danger of making taxonomy an ultimate aim of the subject. There are signs that physical anthropology to-day is slowly freeing itself from this long-standing obsession and is taking as its task the whole biology of man in its social and natural context. Racial and genetic constitution is a very important aspect, but yet only a part, of the variability and adaptability which, in relation to the activity and efficiency of human groups, it is the task of physical anthropology to elucidate.

J. S. Weiner

EDUCATION FOR MARRIAGE

Marriage

A Book for the Married and the About to be Married. By Kenneth Walker. (Published for the British Social Biology Council.) Pp. xii+136. (London: Secker and Warburg, Ltd., 1951.) 8*s*. 6*d*. net.

THE author, who is a distinguished genito-urinary surgeon and is also well known for contributions of a more philosophical kind to the field of biology, has taken the model of a guidebook for those about to be married and has transformed it into something much more rich and interesting. Prejudices on the subject of human sexual behaviour are so strong that it must be the greatest temptation to avoid controversial issues when writing a book meant to be read by all and sundry. Mr. Walker evades none of the difficult points, deals with them with frankness and courage, and does not gloss over his personal views, however unconventional he may feel them to be. When discussing pre-marital continence, for example, he points out that in Western societies the average age at marriage has been steadily pushed back until it is now about thirty. "This means that for at least a dozen years young people are compelled to suppress an instinct which is only second in intensity to that of self-preservation."

No reversal of this tendency to postponement can be expected. Every individual must find his own answer to the problem he is set in this way. It is one thing to be restrained from pre-marital sexual relations by genuine convictions; but quite another to be held back by mere fears, fears of women and sexuality in general, fear of scandal, fear of being found incompetent, fear of going too far. "It is these youths, outwardly continent and inwardly unchaste, who are likely to develop a neurosis in the course of their struggles."

The author points out that in his treatment of this and other difficult topics in the course of the book he does not speak for its sponsors, the British Social Biology Council, but for himself alone.

From the first chapter, on marriage and the family, including their biological and social justifications, to the last, the wider aspects of the theme are tackled with vigour and from a strongly personal point of view. The result is a book which is marked by the personality of the author, is stimulating and refreshing to read, and will surely compel the intelligent reader to do some thinking on his own account. The more purely factual matter—the anatomical and physiological discussion of sexual function—is, of course, expert and accurate. On territory which is factually less safe, there will certainly be readers who will be provoked to differences of opinion, not only on religious but also on anthropological and sociological grounds.

Eliot Slater

Remington's Practice of Pharmacy

A Treatise on the Preparing, Standardizing and Dispensing of Official, Unofficial and Extemporaneous Pharmaceutical Products, with Descriptions of Medicinal Substances, their Properties, Uses and Doses. Tenth edition, by Dr. E. Fullerton Cook and Dr. Eric W. Martin. Pp. xii+1616. (Easton, Pa.: Mack Publishing Co., 1951.) n.p.

THIS is a new edition of a standard work, one of the editors being Dr. Fullerton Cook, who was chairman of the Committee of Revision of the Pharmacopeia of the United States for thirty years. It deals with the whole art and science of pharmacy, as it is practised in the United States. After a general section on such themes as history and ethics, it describes the technical operations used in the laboratory and the factory. About eight hundred pages are devoted to descriptions of the substances and preparations used as drugs, including all those which are official in the United States and many unofficial ones. This edition includes valuable sections on the uses of drugs contributed by Prof. L. S. Goodman, of Salt Lake City.

The field covered is reasonably up to date, but it is curious to note how American practice differs in details from British practice; for example, the list of antihistamines contains more than fifty preparations, but promethazine does not appear to be mentioned even under the guise of some other name. The section on testing and analysis contains an interesting article on statistics by Lila F. Knudsen. There are sections on the laws governing pharmacy, on professional details such as furniture, first aid and contraceptives, on business methods, on the art of perfumery and the treatment of poisoning.

This bulky book appears to contain almost all that the American pharmacist needs to know. Ten editions have appeared at irregular intervals during sixty-five years, and the last interval was only three years. The book evidently continues to serve a useful function after all this time.

J. H. G.

Physical Chemistry, Experimental and Theoretical

An Introductory Text-book. By Dr. G. Van Praagh. Pp. xiv+295. (Cambridge: At the University Press, 1950.) 15*s*. net.

ALTHOUGH called experimental and theoretical, this book is mainly a laboratory manual of physical chemistry. A certain amount of theoretical matter, discussing and integrating the principles illustrated, is adroitly blended with the groups of experiments. This is a good practice and helps to promote a mastery of the subject.

In selecting his experiments, Dr. G. Van Praagh has carefully kept in mind the limits of time and apparatus usually found in schools. Moreover, he has tried out the whole of the two hundred experiments described. These cover the states of matter (including the colloidal state), atoms and molecules, solutions, adsorption, chemical change, mass action, ionic dissociation, phase reactions, and electrochemistry. The informative value of the experiments chosen, the good distribution over various topics, and the balance kept between the easy and difficult, all combine to make this an excellent book for use in colleges and the advanced forms of schools.

My only adverse criticism is not of the method or contents but of the author's attitude to his indebtedness for information. He does not state why he only occasionally mentions the originator of an experiment; for many of his experiments are taken from other instructional books, and in some of these books they are described for the first time. Yet Dr. Van Praagh makes no mention of permission in the preface or acknowledgment in the text.

G. FOWLES.

Cumacés

Par Prof. Louis Fage. (Faune de France, 54. Fédération française des Sociétés de Sciences naturelles: Office central de faunistique.) Pp. iii+136. (Paris: Paul Lechevalier, 1951.) 1200 francs.

THE latest publication in the well-known "Faune de France" series, No. 54, is by Prof. Louis Fage and deals with the crustacean order Cumacea. The name Cumacea, given by Krøyer in 1846, was based on the genus *Cuma* established by Milne-Edwards in 1829 for *C. audouini*; but the name is preoccupied by *Cuma* for a mollusc given by Humphrey in 1797. In spite of suggestion by Stebbing in 1900 that the order should be renamed Sympoda, it is still more general, as in the present work, for the older name to be used. For forty-three years *C. audouini* remained the only species of the order known from France; but the present work deals with sixty-seven valid species from France after excluding doubtful records, and, as the author suggests, more of these small forms are likely to be added as time goes on.

The first twenty-two pages provide an account of the structure, biology and other general matters; the remainder is devoted to systematics. The latter includes useful keys of the descending categories down to species and a full, diagnostic description of each species. The brochure is illustrated with 109 text-figures, many of which contain a number of individual drawings. While not incorrect under the International Rules, the reviewer considers it preferable to follow the general practice of writing the trivial name with a small initial letter when it is derived from the name of a person.

Die botanische Buchillustration

Ihre Geschichte und Bibliographie. Von Claus Nissen. Band 1: Geschichte, Lieferung 2. Pp. 81–160. Band 2: Bibliographie, Lieferung 2. Pp. 81–160. (Stuttgart: Hiersemann Verlagsgesellschaft m.b.H., 1951.) n.p.

THE second parts of the two volumes follow the lines of the earlier parts. The author and publishers are to be congratulated on their speedy appearance, and the hope may be expressed that publication will soon be completed. This part of the first volume, dealing with the history of botanical book illustration, completes the chapter on what is termed the baroque period and then passes on to the modern period which, starting with Robert Morison, ends with issues of King Penguins and Pelicans. Pride of place is given in this period to British publications, although some of the best botanical artists whose work is discussed were not of British birth, as, for example, Ehret and the Bauer brothers. The second part of the second volume, dealing with bibliography in alphabetical order, carries on from *He* to *Sa*. As in the first part, one notes some surprising omissions. For example, under Prain there is no reference to the fine work by Prain and Burkill on the genus *Dioscorea* in the East, published in the *Annals* of the Royal Botanic Garden, Calcutta, 1936, while Vol. 2, "Monocotyledons" (1934), of J. Hutchinson's "Families of Flowering Plants" is also omitted.

W. B. T.

WEATHER AND THE MOVEMENTS OF LOCUST SWARMS: A NEW HYPOTHESIS

By Dr. R. C. RAINEY
Desert Locust Survey Headquarters, Nairobi

MIGRATING locust swarms have attracted attention since the earliest times, and recent evidence has fully established the spectacular nature of some of these movements. Thus, following the heavy locust breeding experienced on the Red Sea coast of Saudi Arabia between February and April 1950, the first wave of desert locust (*Schistocerca gregaria* Forsk.) swarms to reach the Nile valley during the present plague appeared near Atbara on May 17, 1950, and were reported in Darfur, some seven hundred miles away to the west-south-west, fifteen days later. A detailed examination of the evidence leaves little doubt that these swarms had, in fact, originated on the Arabian coast, and that it was some of the same swarms which afterwards reached the Ouaddai area of French Equatorial Africa in mid-June, representing a total net displacement of some 1,300 miles in about a month. An illustration of the distance which may at times be covered in a single flight is provided by two well-documented records of numbers of desert locusts coming on board ships in the Atlantic some 1,200 miles from the nearest land[1,2].

The importance of the wind in the dispersal of air-borne insects in general has often been stressed (ref. 3, etc.), and the part played by the wind in such swarm movements as those mentioned is indicated by the off-shore wind, which reached gale force at times, associated with the only one of these ocean records for which adequate weather data are available[4], and by the fact that certainly the greater part and probably the whole of the movement across the Sudan during May–June 1950 took place down the north-east monsoon. Moreover, while prolonged flight has been regarded[5,6] as characteristic of the behaviour of gregarious adult locusts, field[7,8] and laboratory[9,10] determinations of the air-speed of flying locusts over a considerable range of conditions have given mean values ranging from 7 to 11 m.p.h., which at once set very modest upper limits to the wind-speeds against which swarms may be expected to be capable of making headway.

Furthermore, while there are a number of records of locusts landing into the wind, and turning out of winds in excess of flying speed (probably both optomotor reactions[6]), and of taking off into wind (probably involving the aerodynamic sense-organ[7,11]), field observations have so far failed to find any fixed and consistent orientation of flying locusts to potential orientating factors such as wind and sun. Thus, in winds of less than the probable air-speed of the locusts, up-wind, down-wind and cross-wind orientations are all observed[6,7,12]. Moreover, a swarm failing to maintain any persistent orientation, either circling (a form of swarm movement not infrequently seen), or even changing course sufficiently frequently at random, would also be displaced down-wind. On this evidence, swarm movements in directions other than down-wind would appear likely to be of limited extent, of the order of a few miles a day, and to occur only in areas and seasons of light winds.

This is in general agreement with most of the regular major seasonal movements of swarms so far described in, for example, the Indo-Pakistan area[13] and eastern Africa[5], which take place down the corresponding prevailing winds, and change direction with them. Furthermore, certainly some of the exceptions to this generalization, and possibly all, may well represent movements down non-prevailing winds. Thus perhaps the most striking of these exceptions is the northward movement of swarms in spring to the countries of North Africa and the Middle East[6,14,15], against the direction of the corresponding prevailing northerly winds. At this season, however, all the territories concerned, from Morocco to Baluchistan, are intermittently affected by depressions, moving eastwards and characterized by the temporary interruption of the northerlies by warmer winds from a southerly quarter[16], the subsequent re-establishment of the cooler northerlies often taking place at a well-marked cold front[17,18,19]. An association between the arrival of swarms in Egypt and the passage of depressions has long been recognized[20], and an example of a similar association was provided by the heavy invasion of Tripolitania in early 1951; the main wave of swarms arrived during January 29–30, with the strong south-westerly winds that developed ahead of the primary cold front of one of the deepest and most active depressions of the winter. Rao[21] has similarly attributed northerly and north-easterly swarm movements in spring in Baluchistan to down-wind displacement in the warm sectors of passing depressions. The higher temperatures associated with the southerly winds in the warm sectors of such depressions thus appear to operate as a 'rectifying factor'[6], favouring displacement in a northerly direction. A further example of a frequently recorded swarm movement which probably takes place down a non-prevailing wind is provided by the swarms landing on the north coast of the Somali peninsula during the south-west monsoon. Such swarms have been shown[22] to be probably mainly of local origin, returning with the well-marked afternoon sea-breeze characteristic of this area and season, after having been swept out to sea by the strong morning monsoon.

It has accordingly been found useful to examine some of the meteorological implications of down-wind movement. A synoptic chart, recording simultaneous observations of weather over a wide area, demonstrates areas of convergence, across the boundaries of which surface winds show a net excess of inflowing air over outflow, and within which the overall vertical motion of the air is one of ascent; and areas of divergence, across the boundaries of which outflow exceeds inflow, and within which the overall vertical motion of the air is one of descent. Convergence is an essential factor in the production of widespread heavy precipitation, while divergence is generally associated with fair weather; and the recognition and characterization of such areas is accordingly an essential step in the process of weather forecasting. Examples of areas of convergence affecting regions invaded by the desert locust are the Inter-tropical Convergence Zone (refs. 23, 24, etc.), between trade-wind and monsoon currents originating on

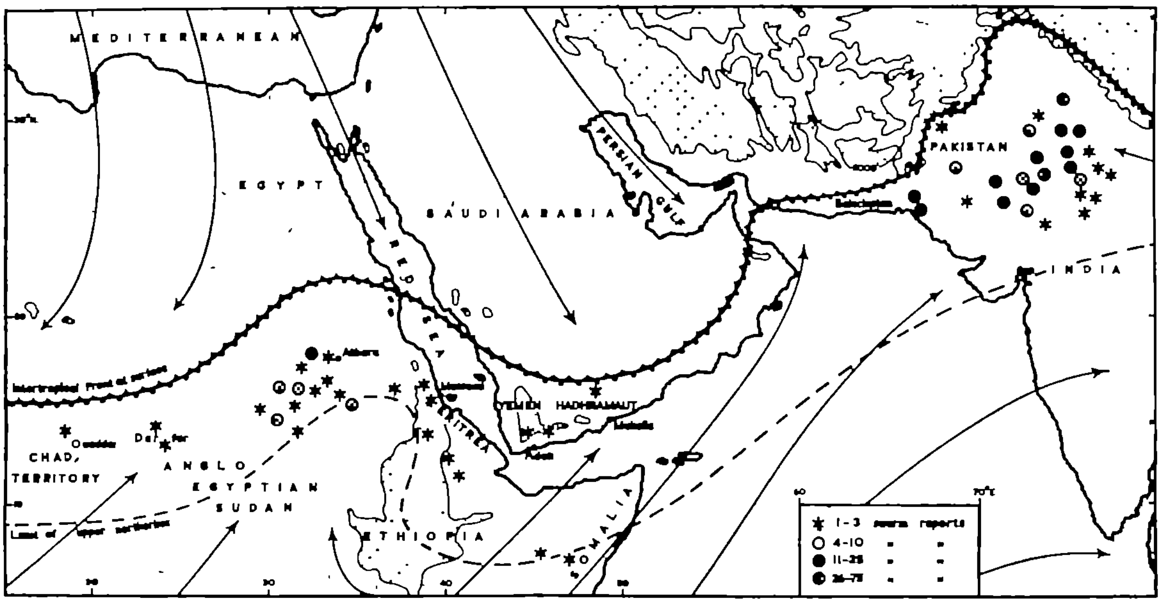

Fig. 1. The Intertropical Convergence Zone and the distribution of desert locust swarms, July 12–31, 1950

opposite sides of the equator, associated with the 'short', 'long' and 'monsoon' rains of most of Africa and India; the westerly depressions already mentioned which give the winter and spring rains of the Mediterranean and Persian Gulf (ref. 16, etc.); and the semi-permanent front, between north-westerly and south-easterly winds, associated with the winter rains of the central and southern Red Sea (refs. 17, 25). Now, in general, winds within a few thousand feet of the earth's surface may be regarded ultimately as blowing from areas of divergence to areas of convergence; and displacement down-wind may therefore be expected to result in movement sooner or later into areas of convergence. It is therefore suggested that the major displacements of locust swarms take place towards areas of convergence, and that swarms may in general be expected to collect in the vicinity of such areas.

This hypothesis may readily be tested by a comparison of swarm records with the corresponding current synoptic charts. In dealing with records from thinly peopled regions, such a comparison is most conveniently made over a period of a number of days during which the synoptic situation is showing little change, in order to be able to consider a number of swarm reports sufficiently large to be representative of the current swarm distribution. The first such period examined was July 12–31, 1950, when the Intertropical Convergence Zone remained relatively stationary in the position indicated in Fig. 1, which also gives the distribution of all desert locust swarms reported during this period, together with an indication of the corresponding surface winds. It will be noted that all the swarms reported were in the vicinity of the Intertropical Convergence Zone, from Chad Territory in the west, through the Anglo-Egyptian Sudan, Eritrea, Ethiopia, Yemen, the Somalilands, the Aden Protectorates and Pakistan to northern India. Practically all recorded swarms were, in fact, between the position of the air-mass boundary at the surface (the Intertropical Front) and the southern limit of the over-running upper northerlies (the 'limit of deep monsoon air'[26], or 'nose of the Intertropical Front'[26]), which at this season is usually closer to the main zone of precipitation than is the surface Intertropical Front[25,26,27]. During this particular season, both the Intertropical Convergence Zone and locust breeding were incidentally recorded as extending considerably farther north than usual in the Anglo-Egyptian Sudan, and the Intertropical Convergence Zone was, as indicated in Fig. 1, probably also farther north than usual over Arabia.

Such evidence of an association of swarm distribution with the Intertropical Convergence Zone encouraged the hope that the movements of the latter might prove to be associated with some of the corresponding swarm movements. The first opportunity of investigating this possibility was provided by the swarm movements in eastern Africa during September and October, 1950, including the first invasion of the British East African territories during the present plague (Fig. 2).

During most of September, 1950, the only desert locust swarms reported south of the Gulf of Aden were in the western end of the Somaliland Protectorate, with the adjacent parts of Ethiopia, where breeding had occurred during the previous month, and near Erigavo in north-eastern Somaliland, where swarms had been present since early August.

During the fourth week of September the Intertropical Convergence Zone began to move southwards from the Gulf of Aden across the Somalilands, with surface north-easterlies established for the greater part of each day at Djibouti from September 22, at Berbera from September 23, and at Hargeisa from September 26; on September 27 a large swarm was reported in south-eastern Somaliland at Las Anod, where 2 in. of rain had been recorded the previous day. On September 29 and 30 rain was recorded in the neighbouring parts of Somalia and of the Ogaden; and on October 1 immature swarms were seen in this area, near Gardo. Away to the west, swarms were reported on September 30 to have left Durdur, where breeding had been particularly heavy, in a southerly direction; and on October 1 a swarm was seen near

Fig. 2. Advance of the Intertropical Front and the movement of desert locust swarms in eastern Africa during September and October 1950

Giggiga, to the south of the Borama-Bio Caboba area, in which a number of young swarms had been reported during the latter half of September. By October 2 northerlies were established at Gardo, and for the next few days the Intertropical Front remained between this station and Gallacaio, still in south-westerlies. On October 3 an immature swarm was seen and heavy rains fell between Gardo and Gallacaio; there was further rain at Gallacaio on October 4; and on October 6, following freshening north-easterlies at Gardo and Hargeisa, swarms were seen to the south-west of Gallacaio.

Following a temporary recession of the Intertropical Front, with south-westerlies re-established at Gardo between October 7 and 11 and at Hargeisa between October 8 and 10, its southward movement was resumed, with surface north-easterlies on the afternoon of October 11, with gusts up to 20 knots at Gardo and reaching 15 knots at Hargeisa. On this date flying locusts were seen from an aircraft at 4,500 ft. over Wardere, and an immature swarm was reported between Giggiga and Dagabur; on October 12 there were two further reports of immature swarms, south and south-west respectively of Dire Dawa.

The south-westerlies receded from Gallacaio and Gumburo (I am indebted to the Sinclair Petroleum Co. for the Gumburo records) after October 18 and from Belet Uen after October 19; easterlies were established at Gallacaio on October 20, with rain, continuing on October 21, when showers were also recorded at Belet Uen. Easterlies were temporarily established at Gumburo during October 19–21, with 2·2 in. of rain on October 20. On October 18 a heavy invasion of mature swarms began in the Dusa Mareb area, between Gallacaio and Belet Uen, and during October 20–25 widespread egg-laying took place in this area, where heavy rains also fell at about this period.

The Intertropical Convergence Zone continued to move southwards, with the establishment of northerlies at Belet Uen and of north-easterlies at Gumburo on October 24, and of north-easterlies at Mogadiscio and easterlies at Bardera by October 25; on October 24 flying swarms were reported at Oddur, between Belet Uen and Bardera, and near Bulo Burti, between Belet Uen and Mogadiscio.

On the night of October 25–26, scattered locusts flew over Lugh Ferrandi; on October 26 there were the strongest north-easterlies of the month at Belet Uen and Mogadiscio, widespread showers occurred in Kenya, and swarms arrived at three points in the Mandera area. On October 27, easterlies had become established at Mandera, and swarms were reported near El Wak and at Bur Acaba, again very close to the limit of the surface north-easterlies in these areas.

The Intertropical Convergence Zone became relatively stationary and generally inactive during most of November, with no further sustained southward movement until early December. There were signs of increased activity during mid-November, with rains on November 11 and 12 in south-central Somalia and north-east Kenya; and on these dates swarms reached the Merti (Kenya) and Dugiuma (Somalia) areas, the most southerly points known to have been attained by this generation; both areas were in the immediate vicinity of the Intertropical Front at the time.

The north-easterlies usually over-run the retreating south-west monsoon in East Africa[24], as elsewhere in the region under consideration[25-28], and were, for example, established at 7,000 ft. above sea-level over Kenya as far south as the equator when they had only reached 5° N. in Somalia at the surface. Plateau-level north-easterlies and rains were, in fact, experienced at times well in advance of the southern limit of the surface north-easterlies of the lowlands. The leading swarms, however, remained in the immediate vicinity of this latter limit (the Intertropical Front) throughout the migration; the beginning of the southerly swarm movement from Somaliland, for example, and the arrival of the first swarms in Kenya, five hundred miles away and a month later, both appear to have taken place within a day of the passage of the Intertropical Front across the areas concerned. Over this period the speed as well as the general direction of displacement of the leading swarms thus appear to have been determined by the movement of the Front.

The hypothesis that major swarm movements take place towards, and with, zones of convergence thus appears to merit further consideration as a potentially useful means of supplementing the present essentially historical method of forecasting swarm movements, since forecasts of the movements of the Intertropical Convergence Zone over central Africa, for example, based on the pressure distribution to the north and south of the continent, are issued by the East African Meteorological Department up to a week ahead. The hypothesis may well indicate a need for further information on limiting conditions for flight, which are likely to be important, for example, in determining the speed of swarm displacements approaching zones of convergence from a distance. It may, in addition, help to provide a background against which the finer effects of behaviour on displacement may be more effectively studied, by enabling appropriate allowance first to be made for the part played by the purely transporting effect of the wind in particular recorded swarm displacements.

Convergence also provides a mechanism for the frequently recorded association of exceptional rains with the arrival of locusts; during November–December 1949, to quote a single example, the first swarm record anywhere in Arabia after a lapse of four months, at Mukalla, with the first full-scale gregarious breeding in the Hadhramaut during the present plague, followed a rainfall of 7 in. in 36 hr. at this station, for which the mean annual rainfall, over the whole nine years for which records are now available, is 2·5 in. A similar effect (I am indebted to Mr. P. R. Stephenson for this suggestion) may perhaps also contribute at times to the process of gregarization, by producing a measure of 'real concentration'[29] of adult *solitaria* from long distances into limited areas which provide suitable conditions of moisture and vegetation for breeding. Thus in late November 1950, for example, scattered locusts, at densities ranging from 1 to 100 per 100 yd. of traverse, were encountered in uniformly dry conditions at a series of points extending along 58 miles of the Eritrean coast near Massawa, while on a second reconnaissance over the same route a fortnight later locusts were found, at densities of 400–600 per 100 yd., only within the eight-mile stretch to which rains in the meantime (totalling 5·6 in. at Massawa) had been restricted[30]. This mechanism may well be of vital importance to the continued existence of species such as the desert locust, inhabiting regions of scanty and erratic rainfall with an egg-stage almost aquatic in its moisture requirements[31], and moreover suggests a possible survival value of flight without consistent orientation for other insects.

The data used in this work have been made available by the co-operation of the meteorological services and of the locust control and research organizations of the whole area considered, from French Equatorial Africa to India. I am furthermore particularly indebted to members of the forecast staffs of the meteorological offices at Aden, Asmara, Cairo, Djibouti, Ismailia, Karachi, Khartoum, Mogadiscio and, particularly, Nairobi, for the benefit of their synoptic experience; to Dr. B. P. Uvarov, of the Anti-Locust Research Centre, and Mr. P. R. Stephenson, of the Desert Locust Survey, for their support and active interest in this investigation; to Miss Z. Waloff and Messrs. Y. R. Ramchandra Rao, K. F. Sawyer, W. J. Stower, T. Weis-Fogh and N. W. Wootten, for the use of unpublished data; and to members of the Nairobi Scientific and Philosophical Society, for their comments on the hypothesis at the Society's meeting of November 21, 1950.

EXPERIMENTS ON THE HIGH-ENERGY NUCLEONS AND QUANTA*

By SIR JOHN COCKCROFT, C.B.E., F.R.S.

EXPERIMENTAL nuclear physics is to-day moving into a very exciting new phase, the phase in which we are attempting to discover the nature of the forces between the so-called elementary particles of matter, in particular the forces between the nucleons—protons and neutrons—of which atomic nuclei are made up. We wish to know the relations of these forces to the twenty or so other elementary particles which have been discovered within the past two decades or are due for discovery in the near future.

Before I embark on this, it is worth while to look back at the first three ages of nuclear physics.

The Ages of Nuclear Physics

The first age, which will for ever be associated with the Curies and with Rutherford's work at McGill, saw the discovery of radioactivity and of radioactive change; the discovery that the heavy elements are unstable, changing gradually through the emission of electrons and α-particles—or helium nuclei—to lead.

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on November 2.

The second age gave rise to the conception of the nuclear atom. In this age, which was coincident with Rutherford's Manchester days, experimenters in his laboratory studied the interactions of high-speed α-particles from radium with matter. Geiger and Marsden showed that these particles could be reflected backwards from metal surfaces—an observation which, as Rutherford said in later years, was to him as surprising as if a 15-in. shell had bounced back from a sheet of tissue paper. He calculated the enormous magnitude of electric or magnetic fields required to produce this repulsion of the particles, and from this came to his conclusion that such forces could only be provided by a nuclear model of the atom in which the greater part of the mass and an electric charge proportional to the atomic number is concentrated in a central core of the atom having a diameter of the order of 10^{-13} cm.

Within this age there developed also the remarkable work of Niels Bohr, which explained the stability of the electron orbits outside the nucleus; and the work of Moseley, which showed that the electronic structure and the chemical properties of the elements depend on the nuclear charge.

The third age opened with the discovery by Rutherford that the nuclei of the light atoms could be penetrated and transmuted by his high-speed α-particles. The forces near the nucleus were shown to be represented by the electrostatic forces corresponding to a central charge Ze, provided the exploring particles did not approach closer than 10^{-13} cm. to a nucleus. If they came closer, the forces could no longer be so represented, showing that inside the nucleus we had to do with a different realm—a realm scarcely explored in this third age.

The scope and scale of Rutherford's disintegration experiments were enormously extended by the invention of particle accelerators designed to accelerate hydrogen and deuterium nuclei, and so provide for the physicist streams of atomic projectiles a million-fold greater in intensity and exceeding in energy the α-particles available to Rutherford. These accelerators consisted of three main types: the voltage multiplier type of generator associated with Prof. E. T. S. Walton and myself; the Van de Graaff electrostatic generator; and the cyclotron of Prof. E. O. Lawrence. This age has been called by some the Golden Age of Nuclear Physics; by others—whose dreams reach far into the future—the Stone Age.

One of the greatest achievements of the Golden Age was the discovery of the neutron by Chadwick. This led to a new concept of the internal constitution of the nucleus, which was now thought of as consisting of an assembly of N neutrons and Z protons:

$$Z + N = \text{isotopic weight.}$$

This close-packed assembly of nucleons was seen to require a new kind of inter-nucleon force to hold it together, for the disruptive effect of the positive electrostatic forces of the protons is enormous. If, for example, we consider the 92 protons of a uranium nucleus to be distributed half on each hemisphere of a nuclear surface of radius 10^{-12} cm., a simple calculation shows that there will be a disruptive pressure of about 10^{23} atmospheres. There must therefore be counterbalancing attractive forces between nucleons which prevent the nucleus from blowing up.

Since these forces act between uncharged neutrons and charged protons, and presumably between pairs of neutrons, these forces cannot be electrical or magnetic in origin. The discovery of their nature is one of the major problems of the new age.

I should also recall the discovery of the first of the transient or short-lived elementary particles—the positive electron, discovered first in cosmic rays by Anderson. Blackett and Occhialini obtained beautiful pictures of the creation of pairs of positive and negative electrons, while Chadwick and Goldhaber showed that the electromagnetic radiation of the gamma-rays could create these pairs. The creation of matter from radiation, and its inverse—the annihilation of the positive electron to produce radiation—was established.

The closing years of this age saw the discovery of nuclear fission and its sombre consequences.

Nuclear Forces

If I turn now to the post-war developments—the fourth age—our major interests are focused on the nature of the forces which hold the nucleus together, and on the nature of the new members of the family of so-called elementary though transient particles which workers in the cosmic ray field present to us year by year. We believe that these transient particles are closely connected with the intense forces acting between nucleons.

The experimental nuclear physicist attacks the problem first with the classical methods. If a nucleus such as beryllium consists of four protons and five neutrons bound together by the nuclear force, he fires into these nuclei streams of neutrons, or alternatively streams of protons, sufficiently energetic so that the electrostatic forces of repulsion outside the nucleus will be negligible. We can then study, in the classical way, the angular distribution of particles coming *out* of the nucleus. We can think perhaps of the nucleus as a snooker pool of red and white balls, into which we fire either a red ball or a white ball, and look for the angles of emergence of the balls struck.

The high-speed neutrons and protons used in this type of experiment are most conveniently produced by the cyclotron, and the Harwell cyclotron is typical of several machines built for such studies. This machine has been built and operated by a group at Harwell led by Pickavance, Cassels, Taylor and Dickson. The cyclotron produces an internal circulating beam of about one micro-ampere of protons (or 6×10^{12} protons/sec.) which can attain an energy of 180 million electron volts if they are allowed to spiral out to full radius. If a target interrupts their path at a smaller radius, the final proton energy is correspondingly reduced. We can therefore carry out experiments over a wide range of proton energies.

We can also extract part of the beam by scattering it from a thin uranium foil into a channel screened from the magnetic field of the accelerating space. The protons can then escape from their spiral orbit and are directed down a long pipe to the experimental chamber situated beyond thick concrete walls. We have about 2×10^{5} protons/cm.^{2}/sec. coming out of the end of the pipe, 40 ft. from the cyclotron.

When we wish to produce high-speed neutrons for experiment, we allow the protons to strike a target of beryllium—our snooker pool of four protons and five neutrons, if I may return to the simile. We find then that neutrons are projected forward with practically the full energy of the impacting proton—180-MeV. protons produce some neutrons of 178-MeV. energy. This can only happen if our striking nucleon makes a head-on shot on a neutron, knocking it forward with full momentum and coming to rest itself. In order to be able to do this, it must not disturb the rest of the balls of the snooker pool.

At Harwell the neutrons pass out of the vacuum chamber of the cyclotron, through tubes in the 15-ft. shielding blocks of concrete and so into a long experimental tunnel. The highly collimated beam of neutrons then strikes a thin disk of polythene $(CH_2)_n$ from which hydrogen nuclei or protons are ejected. These protons have in turn almost the full energy of the neutrons, and by measuring their energy spectrum we determine the neutron energy spectra.

We look, therefore, for these protons at an angle of projection of 10° and arrange there a so-called 'telescope' of three counters which operate an electronic register when a particle passes through all three.

We can now introduce a disk of graphite between the second and third counter; when its thickness is equal to the maximum range of the protons in graphite, we cease to record protons passing right through the telescope. The graphite disk enables us, therefore, to determine the energy of our protons, just as thin slips of mica—so thin as to show interference fringes—enabled us to measure α-particle energies in the 'Golden Age'. The comparison of the thin mica films with the graphite disk illustrates directly the great increase in particle energies since the 1932's.

We can therefore measure the energy spectra of the protons and hence deduce the energy spectra of the neutrons projected out of the beryllium target. The result is a peak of almost the full energy, indicating that a large fraction of the protons transfer their full momentum to a single neutron. This shows that the incoming proton does not interact with most of the other nucleons, otherwise some of its energy would go to them. Hence also the range of action of the nuclear forces must be small—smaller than 2×10^{-13} cm.—otherwise the fast proton would transfer some of its energy to other nucleons.

However, there is a tail of neutrons of lower energy. If we replace the beryllium target by an aluminium target, the tail becomes much more prominent. Since we are all the time observing neutrons projected in the forward direction, this must mean that some of the struck neutrons make small-angle multiple collisions in the snooker pool of the nucleus before emerging.

We can compare these results with those of the Harvard workers, who use 110-MeV. protons. The peak for the Harvard experiment is much more pronounced when the lower-energy protons are used. This can be explained by the fact that neutrons of energy less than about 90 MeV. do not escape easily from the nucleus, whereas neutrons of higher energy do escape because of a curious interference effect. The neutron spectrum is therefore filtered in favour of high-energy neutrons. The carbon nucleus is more tightly bound; the threshold energy for neutron production is about 20 MeV. and so no neutrons more than 90 MeV. are produced. No peak is found in the Harvard results for carbon.

We find also that neutrons of much lower energy emerge from the nuclear pool. Mrs. Skyrme has looked for these by a quite different technique. The direction of the proton beam was reversed. She then investigated the backward direction for low-energy neutrons by means of photographic plates, and found another substantial peak having a maximum at about 1 MeV. neutron energy. These neutrons result from a general transfer of energy from some protons to the whole nuclear pool. The nucleus is 'heated up' to a temperature corresponding to a million volts, or about 2×10^{9} °C. Neutrons then evaporate and the evaporating neutrons have a Maxwellian spectrum. On the average, about four neutrons evaporate from a tungsten target for each striking proton which loses energy. When light targets are used, less than one neutron evaporates for each collision. We have therefore the two mechanisms of transferring energy: the single-shot, head-on collision with one nucleon; the second, the 'bosh shot' which heats up the whole pool and leads to neutron evaporation.

The next experiment studied the angular deflexions in collisions of the high-energy neutrons with the protons of the polythene disk. We are dealing here with the collisions of nucleons of almost the same mass. If the nucleons were to behave like minute elastic billiard balls, we would expect that in the centre-of-gravity co-ordinates—thinking of the two balls moving towards each other with half velocity—all directions would be equally probable after the collision.

If, then, we were to plot the number of neutrons emerging from the collision at different angles per unit solid angle, the number would be constant for all angles. Actually, we observe quite a different distribution. There are far fewer protons emerging at 90° than at 180°, and there is not even symmetry about 90°. Our nucleons do not therefore behave like minute elastic billiard balls.

We next use 145-MeV. *protons* as exploring projectiles. To do this we move our experiment to the other side of the cyclotron—to use the protons coming down the long pipe. Again we look for projected protons, and can at the same time look for the deflected striking protons which should emerge at right angles. Actually, they do not emerge quite at right angles—since the striking protons are moving quite fast they are slightly heavier because of relativity, and the angle after the collision is observed to be slightly less than 90°.

We find now that protons colliding with protons do behave like elastic billiard balls, at any rate down to angles of about 30°. However, this difference does not show immediately that the forces between protons and protons and those between neutrons and protons are different. The reason is that the Exclusion Principle modifies the proton–proton collisions, but not, of course, the neutron–proton collisions. It is still a matter of controversy whether these high-energy experiments do provide evidence for such a difference, but recent work at rather lower energy (14 MeV.) suggests that it does, in fact, exist.

Another question raised by the high-energy work, to which Berkeley (345 MeV.), Rochester (240 MeV.), and Harvard (110 MeV.) are also contributing, is the following: Is it possible to explain all the observed effects by the use of forces which do not vary with the relative velocity of the particles? Here the answer appears to be 'No', although theoretical investigation continues. Theoretical physicists have tried to find a potential of interaction representing an attractive force at large distances and a repulsive—hard core—force at short distance. They then vary the parameters in order to achieve a fit with results. This is the so-called 'phenomenological approach'. So far this approach has not been very successful, in that the curves calculated for the angular distribution after the collision, however much adjusted by variation of parameters, cannot achieve a good fit.

In these circumstances it seems scarcely fair to set a still more difficult problem of nuclear dynamics to the theoretical physicist. The cyclotron group has, in spite of this, studied the collision of high-speed protons with nuclei of heavy hydrogen, which consist of one proton and one neutron, so that we may have a three-body interaction.

The scattering curves found are quite different from either proton–proton or proton–neutron scattering. An explanation of this will have to await the solution of the two elementary processes already considered. The next, and more difficult, step in the experiments is to study the scattering of neutrons by deuterons. A comparison between the results for proton–deuteron and for neutron–deuteron scattering should then enable us to say whether the neutron–proton and proton–proton interactions are similar. This seems to be the most direct way of obtaining information about neutron–neutron forces, since the scattering of neutrons by neutrons cannot be observed.

At this stage we should inquire whether there is not some other influence affecting these collisions. The obvious particle to suspect is the meson. Mesons were, in fact, invented by the Japanese physicist Yukawa so long ago as 1935 just in order to account for nuclear forces. He suggested the existence of this new particle having a mass such that the wavelength $\lambda = h/mv$ was equal to the expected range of nuclear forces, 2×10^{-13} cm. The new particle should then have about 200 times the electron mass. The mesons then might be considered to be the heavy quanta of the nuclear field.

Soon after this, by a remarkable coincidence, the so-called μ-mesons were found in the cosmic rays by Anderson and Neddermeyer. Although we do not now believe that these μ-mesons, which have 220 times the electron mass, have anything to do with nuclear forces—since the μ-mesons scarcely interact at all with nuclei—the Yukawa hypothesis has had an important stimulating effect. Indeed, in 1947, Powell, by his remarkable photographic plate technique, discovered another kind of meson—the π-meson or pion—which does interact with nuclei. These π-mesons have about 275 times the electron mass. There are three kinds, π^+-mesons carrying a positive charge, π^0-mesons which are uncharged and π^--mesons which are negatively charged. The π^+-meson changes into μ-mesons after a very short life—of the order of 10^{-8} sec. Since then, evidence for heavier mesons has appeared in cloud chamber photographs: there is a ν-meson which can change into a proton and there are k- and τ-mesons.

The connexion of these transient particles with nuclear forces becomes evident as we increase the speed of our nucleons in proton–proton and proton–neutron collisions. We find that as the proton energy rises beyond 200 MeV., π-mesons come out of the nuclear pool as though they were transient sparks struck in the intense fields of close collisions. This method of creation of mesons was discovered first in the huge Berkeley cyclotron. The protons from the cyclotron strike a target of graphite. Photographic plates are exposed near by to record any mesons produced. The Berkeley workers found that both π^+- and π^--mesons were produced, and the numbers increase rapidly as the proton energies increase beyond 200 MeV. The still larger Chicago cyclotron now produces so many π-mesons that they have as many as 1,000 a second emerging from a two-inch pipe through their massive concrete shields.

The Berkeley workers found also that gamma-rays having energies of up to 200 MeV. began to be produced at about the same proton energies as the π^+- and π^--mesons. These gamma-rays were also shown, by a brilliant piece of experimental work, to be emitted in pairs. It was found also that they are more energetic in the direction of the proton than in the opposite direction. This suggested that some particle is projected forward by the protons and that it breaks up into the two gamma-rays. By the well-known Doppler effect, the frequency of the rays coming backwards could be less and so their energy would be less. These particles were assumed to be neutral pions, and this has been abundantly confirmed. They are even more transient sparks than the charged pions, for they last only for 10^{-15} sec.

If we agree that these pions must be connected with nuclear forces, how do we visualize the connexion? In a collision of a proton with a neutron, we think of the two nucleons as surrounded by a meson field just as two electrons are surrounded by an electric field. When they come close together, the proton can emit a positive pion or heavy quanta. This pion is then absorbed by the neutron, which becomes a proton. The overall result is a scattering of the two nucleons, which then change their direction. This is a very nice picture; but until theoretical physics can develop the full meson theory and apply it quantitatively to nuclear collision, we must remain only partially convinced of its truth.

Disintegration produced by High-Energy Nucleus

The nuclear disintegration produced by nucleons having energies of up to 10 million volts resulted in the nucleus splitting into two or three fragments at most, since the energy transferred to the nucleus was not sufficient to dismember it still further. Examples of this type of transmutation were the splitting of a beryllium nucleus of mass 8 into two α-particles and the splitting up of a carbon nucleus into three α-particles.

When nucleons having energies of the order of 160 MeV. are used, much greater energies are transferred to the nucleus and more complete fragmentation occurs.

Nuclear transmutations produced by high-energy neutrons and protons enable new radioactive isotopes to be discovered and the empty spaces in the chart of isotopes to be filled.

Dr. F. D. S. Butement and Mr. R. Shillito at Harwell have used the high-energy neutrons from the Harwell cyclotron for such studies. In typical reactions, the absorption of a neutron by the nucleus is followed by the expulsion of a proton or an α-particle. In this way, for example, two new isotopes of gold having isotopic weights of 201 and 202 were found; they are known as neutron-rich isotopes.

Photodisintegration has been used by Dr. Butement and Mr. Shillito as a second method of producing new radioisotopes. The absorption of a high-energy quantum from the Harwell 23-MeV. synchrotron is often followed by the emission of a proton. By these two methods twenty-six new isotopes have been found. One interesting reaction was discovered and investigated by Dr. J. M. Dickson and Mr. T. C. Randle. It is the production of beryllium-7 by proton bombardment of carbon, according to the reaction:

$$^{12}_{6}\mathrm{C} + ^{1}_{1}\mathrm{H} \rightarrow ^{7}_{4}\mathrm{Be} + 3p + 3n.$$

Beryllium-7 has a long half-life of 53 days, so that its strength builds up over a long period. Now in the cyclotron it is necessary to shield the electrodes from the protons scattered from the targets being used in the experiments described previously. The cyclotron group decided to use carbon for this purpose, thus producing as much as 10^{-6} gm. of beryllium-7 every two months while the cyclotron is being used for its main programme. This beryllium-7 has been extracted by Dr. Butement and has been used as a target in further experiments. Dr. R. C. Hanna has shown that it absorbs slow neutrons very strongly ($\sigma = 10^4$ barn).

I will now describe another group of experiments carried out with high-energy quanta produced by the electron synchrotron at Harwell or by the 17·6- and 14-MeV. γ-rays produced by the well-known reaction of protons on lithium. The synchrotron produces electrons of about 23 MeV. energy, and these electrons produce quanta of X-rays when they strike a target. When these quanta enter a nucleus, they set the nucleus into vibration and transfer the energy of the quanta to it. The nucleus can then break up by emitting one or more particles.

To do this the Harwell workers in Mr. Goward's and Dr. Titterton's groups introduced various elements into the emulsion of the special nuclear photographic plates. The nuclei of these elements absorb a quanta and are disintegrated, and the tracks of the particles are made visible on development.

One group of experiments was devoted to the photodisintegration of light nuclei. They showed that in the photodisruption of the nucleus many different types of nuclei are flung out. They include neutrons, protons, deuterons, tritons, helium nuclei and beryllium nuclei. Dr. Titterton and Mr. Brinkworth exposed plates loaded with the separated light isotope of lithium, namely, lithium-6. When these were exposed to 17·6-MeV. γ-rays, V-shaped tracks were found. It appears that these are due to a neutron being ejected from lithium-6, leaving the radioactive nuclei of lithium-5 behind ·

$$^{6}\mathrm{Li} + h\nu \rightarrow {}^{1}n + {}^{5}\mathrm{Li}.$$

This lithium-5 nucleus is known to have a very short life—of the order of 10^{-21} sec. It breaks up in flight into a proton and helium-4, producing a typical V track. A detailed study of the events shows that in some cases lithium-5 is found in a state having about 2·5 MeV. excess energy.

In another experiment, the plates were loaded with the lithium-7 isotope and again exposed to 17·6-MeV. radiation. Some of these showed the long track of an energetic proton and a very short track of a heavy recoiling nucleus. It appears, then, that the disruption of a quantum ejects a proton from the nuclei, leaving behind a nucleus of helium-6 :

$$^{7}\mathrm{Li} + h\nu \rightarrow {}^{1}\mathrm{H} + {}^{6}\mathrm{He}.$$

Then plates loaded with lithium-7 were exposed to these same 17·6-MeV. gamma-rays. In this case a triton was ejected from the lithium-7 nucleus :

$$^{7}\mathrm{Li} + h\nu \rightarrow {}^{4}\mathrm{He} + \mathrm{T}\ ; \text{ also } {}^{11}\mathrm{B} + h\nu \rightarrow \mathrm{T} + {}^{8}\mathrm{Be}.$$

The fourth experiment, by Goward and Wilkins, studied the photodisintegration of carbon-12 nuclei. In this case the long track of a helium nucleus and heavy V-shaped tracks at one end were found. The ejection of the helium nucleus leaves behind a beryllium-8 nucleus which is unstable and immediately breaks up into two α-particles which recoil in opposite directions. The beryllium-8 nucleus is, however, moving at high speed before it breaks up, so that the two α-particles carry the momentum but diverge due to the mutual recoil.

The fifth experiment, using plates loaded with boron-11, shows a rather similar event. In this case the boron-11 nucleus breaks up into a triton and a beryllium-8 nucleus moving in opposite directions. The beryllium-8 nucleus then breaks up into two α-particles giving the characteristic V-shaped track.

In a sixth experiment, carbon and oxygen were irradiated with gamma-rays having energies up to 80 MeV. Carbon disintegrated into three α-particles and oxygen into four α-particles. On examining how the chances of these disintegrations vary with energy, Goward and Wilkins found that there were two prominent resonances in the energies at which they occur.

Conclusion

I have dealt mainly with the Harwell contributions to this new and exciting field of high-energy physics.

In this field the cosmic ray workers using high-energy particles provided by Nature have been the pioneers, and the schools of Bristol and Manchester have discovered the π-, the k- and τ- and the ν-mesons since the War. The high-energy machines are an essential complement to this work, since it is only by their help that we can investigate nuclear forces and the process of creation of mesons in sufficient detail to arrive at an understanding.

Work is proceeding in many laboratories in the United States and will soon be starting in Glasgow, Birmingham and Liverpool as their powerful new machines come into operation. We can be confident that we have at least a decade of work in front of us as the frontiers of our knowledge of the physical world are still further advanced.

OBITUARIES

Prof. A. L. Mellanby

Alexander Lawson Mellanby, emeritus professor of civil and mechanical engineering in the Royal Technical College, Glasgow, died at Bridge-of-Weir, after a short illness, on November 26.

He was born at Hartlepool on July 3, 1871, and was educated at Barnard Castle School. After an apprenticeship at the Central Marine Works, Hartlepool, he entered Durham College of Science, and graduated B.Sc. with honours. He was awarded an 1851 Research Scholarship and went to McGill University, where he carried out research on the reciprocating steam engine. Returning to Great Britain he was appointed chief technical assistant with T. Richardson and Sons, engineers, of Hartlepool, but after a year left industry to enter the academic profession, in which he remained for the rest of his professional life.

His first appointment in this field was as chief lecturer in engineering at Battersea Polytechnic in 1898. Shortly afterwards he was appointed to the Manchester College of Technology as assistant to Prof. J. T. Nicolson, and took a large part in designing and equipping the laboratories, workshops and power station of that College. In 1905 he was appointed to the chair of motive power engineering at the Royal

Technical College, Glasgow, and was in the service of the College until he retired in 1936. His success in this chair was such that first the Department of Applied Mechanics and later the Department of Civil Engineering were merged with his Department into a single Department of Civil and Mechanical Engineering and Applied Mechanics.

Prof. Mellanby was one of the first to realize the importance of experimental work in engineering courses, and, soon after his appointment to the Royal Technical College, he established a heat engines laboratory, outstanding at that time for its size, range and standard of equipment. In those days technical colleges suffered severely from financial and staff limitations ; but Mellanby saw that, without adequate experimental facilities, the highest levels of teaching and research would never be reached. His own work lay mainly in the field of steam and internal combustion engines. Following on his early work on reciprocating engines he took up an intensive study of the flow of steam through nozzles, and was the author of many papers, some of which were in collaboration with Dr. Wm. Kerr, who later succeeded him in the chair. He took an important part in the work of the Marine Oil Engine Trials' Committee, a joint committee of the Institution of Mechanical Engineers and the Institution of Naval Architects, which carried out a series of authoritative trials on marine oil engines of different types. His services were widely sought as a consultant, and special reference was made to this when the University of Glasgow conferred the LL.D. degree upon him in 1936. He served as a member of Council of the Institution of Mechanical Engineers, and took an active part in the operation of the national certificate scheme for engineering students in Scotland. He was a firm believer in academic institutions maintaining close contact with the world of practice and, at an early stage, fostered the establishment of sponsored research projects for industry.

Intellectually a man of science and professionally an engineer, Prof. Mellanby had the sure instinct of the former for the fundamental factors in a complex problem, and the sound judgment of the latter on all practical issues. He deprecated narrow specialization, whether in courses of study, staff training, experimental method or technical authorship, holding that range was essential to quality of judgment. He made many contributions to technical literature, all of which kept in proper balance and perspective the fundamental and practical issues. He was deeply concerned with the welfare of his students and, long after they had left the College, he followed their careers with interest, always willing to give advice in the solution of problems or a helping hand towards further advancement. Few professors had more sympathy with the struggling part-time student, and nothing gave him greater pleasure than to pick out the really talented from this group and assist them to transfer to full-time courses.

Throughout the long period of his retirement, his activity of mind and body remained unimpaired almost up to the last, and his interest in matters educational and practical was unabated. In him human, social and professional qualities were not only fine but also finely balanced, and they were exercised with a quiet dignity and a true sense of duty and service. He will be very much missed in engineering and academic circles in Glasgow and the west of Scotland, and indeed over a much wider area.

DAVID S. ANDERSON

Prof. Rikiti Sekiguti

PROF. RIKITI SEKIGUTI, formerly director of the Tokyo Astronomical Observatory, Mitaka, near Tokyo, died suddenly from heart failure on August 10 at Kamakura.

Sekiguti graduated at the University of Tokyo in 1907, taking astronomy as his subject. He served in meteorological observatories—at a weather station in Korea, at the Marine Meteorological Observatory at Kobe, and for a time as the head of the Solar Section of the Central Meteorological Observatory. Meanwhile he was sent to Europe for study, and worked at Cambridge with the late Prof. H. F. Newall for about a year. In 1936 he was made a professor of astrophysics in the University of Tokyo and the director of the Tokyo Astronomical Observatory. He taught astrophysics to students of astronomy at the University for more than ten years until his retirement at the age of sixty in 1946. At one time he served in the Government as the head of the Special Education Bureau of the Ministry of Education, and took several important steps for the promotion of scientific research.

Sekiguti's main scientific work was devoted to meteorology and oceanography. He developed solar meteorology by applying Margules's theory to the solar atmosphere. He took part in the solar eclipse of 1936, using a small spectrograph of his own design, and announced the recognition of several new spectral lines.

Sekiguti was a good writer. He published several books in Japanese, "The Sun", "Astrophysics", "Introduction to Astronomy", etc. He was an enthusiastic and hard worker in any subject he took up. The Tokyo Observatory was damaged towards the end of the Second World War, and since then his health had declined. His daughter is married to Dr. Shinichiro Tomonaga, a well-known nuclear physicist.

Y. HAGIHARA

Dr. S. Hill

DR. SYDNEY HILL, who died as a result of a street accident on November 27, in his twenty-eighth year, was educated at Holt High School, Liverpool, and proceeded to the University of Liverpool, where he graduated B.Sc.(Hons.) in 1943 and was awarded the Campbell Brown Fellowship. He joined the staff of Peter Spence and Sons, Ltd., in 1943 and was granted leave of absence during 1945–48 to take up the Fellowship, and was awarded a Ph.D. in 1948 for research work in electrochemistry. This work was the subject of several papers published jointly with A. Hickling in the *Transactions of the Faraday Society* and the *Journal of the Electrochemical Society*. Dr. Hill returned to industrial work and at the time of his death was engaged in further electrochemical investigations. His tragic death at an early age closes a career that held great future promise. He was unmarried.

WE regret to announce the following deaths :

Lord Addison, K.G., P.C., chairman in 1948 of the Medical Research Council, on December 11, aged eighty-two.

Prof. H. S. Raper, C.B.E., F.R.S, dean of the Medical School and professor of chemical physiology in the University of Manchester, on December 12, aged sixty-nine.

NEWS and VIEWS

Civil Engineering at Adelaide: Prof. F. B. Bull

THE appointment has recently been announced of Mr. F. B. Bull to the chair of civil engineering in the University of Adelaide, South Australia. Mr. Bull, who is at present a University lecturer at the Engineering Laboratory, Cambridge, studied at University College, Nottingham, where he took the London (External) B.Sc.(Eng.) with first-class honours. After graduation Mr. Bull worked for a number of years with Messrs. Dorman Long and Co., Ltd., where he was engaged in the design of structural steelwork. Following this he was for four years a lecturer in structural engineering at the Constantine Technical College, Middlesbrough. During the Second World War, Mr. Bull served with the Admiralty Department of Scientific Research, where he led a party of engineers, physicists and naval architects engaged in the experimental determination of the stresses in ships' structures. This programme of trials, which was designed to reveal any differences in structural behaviour between ships of welded and riveted construction, included comprehensive measurements of the forces to which a ship is subjected when in a seaway. Various technical papers on this work have been read to professional societies, and the results of the trials are being published by H.M. Stationery Office. Since the War Mr. Bull has been on the staff at the Engineering Laboratory, Cambridge, where he has been concerned with teaching surveying and the theory and design of structures.

Royal Society: Officers for 1952

THE following have been elected Officers and Council of the Royal Society for the ensuing year: *President:* Prof. E. D. Adrian; *Treasurer and Vice-President:* Sir Thomas Merton; *Secretaries and Vice-Presidents:* Sir Edward Salisbury and Sir David Brunt; *Foreign Secretary:* Sir Cyril Hinshelwood; *Other Members of Council:* Dr. R. W. Bailey, Dr. O. M. B. Bulman, Prof. P. A. Buxton, Sir John Cockcroft, Dr. I. de B. Daly, Prof. E. C. Dodds, Prof. M. G. Evans, Sir Howard Florey (vice-president), Mr. P. Hall, Sir Geoffrey Jefferson, Prof. E. J. Maskell, Dr. W. G. Penney, Prof. H. H. Plaskett, Dr. R. Stoneley, Prof. A. R. Todd, and Prof. J. Z. Young.

National Science Foundation: Officers

DR. CHESTER I. BARNARD, president of the Rockefeller Foundation, has been elected chairman of the National Science Board of the National Science Foundation at its second annual meeting held in Washington on December 3. Dr. Barnard succeeds Prof. James B. Conant, president of Harvard University, who was the first chairman of the Board, having been elected to serve for the initial term which began December 12, 1950. Dr. Edwin B. Fred, president of the University of Wisconsin, was re-elected vice-chairman of the National Science Board. The new chairman and the vice-chairman were elected for two-year terms of office as prescribed by the National Science Foundation Act of 1950. Dr. Barnard, who plans to retire soon from the presidency of the Rockefeller Foundation and General Education Board, was long associated with the American Telephone and Telegraph Company. He was a member of the board of consultants to the State Department on atomic control in 1946 which drafted the Acheson–Lilienthal Report. He was also a member of the Presidential Special Committee on Integration of the Medical Services in the Government in 1946. Dr. Fred has been president of the University of Wisconsin since 1945. He is a bacteriologist, and was chairman of the Advisory Committee on Biological Warfare of the U.S. National Academy of Sciences during 1941–43.

New Engineering School, University of Bristol

ON December 12, at Bristol, the Chancellor of the University, Mr. Winston S. Churchill, laid the foundation stone of the new Engineering School building, in the presence of the Lord Mayor of Bristol, other civic dignatories, many distinguished visitors and members of the University. In a brief ceremony, the architect, Mr. R. H. Brentnall, was presented to the Chancellor by the chairman of Council, Mr. W. R. Verdon Smith. Mr. Brentnall then presented the representatives of the contractors and consultants, after which he handed the Chancellor a set of silver tools with which he laid the stone. In declaring the stone well and truly laid, Mr. Churchill spoke of the great need for hastening the application of the discoveries of science by training men and women for this purpose. He complimented the University of Bristol in devoting its greatest post-war expansion to this end.

The complete building will comprise a central block around two small courtyards, with two large wings, running roughly east and west, to form a magnificent frontage over the City below. The whole building, 690 ft. long, is to be faced in light-coloured brick with its principal features in Bath stone. Of the three main floors, the ground floor will consist of the laboratories of mechanical engineering in one wing, aeronautical engineering in the other, with civil engineering in the centre block. On the first floor, electrical engineering and geology will occupy two wings, with staff and student rooms occupying the central block, where the main lecture theatre forms the division between the two courtyards. The second floor provides lecture rooms and drawing offices and will house the departments of mathematics and theoretical mechanics. Completion of the interim stage is expected in two years.

Lord Rutherford

TO mark the opening of the Rutherford Memorial Appeal in New Zealand, six addresses were delivered at Canterbury University College, Christchurch, on May 18. Three of these were afterwards broadcast. The text of the six addresses is reprinted in the July number of the *New Zealand Science Review* (9, No. 7), the official organ of the New Zealand Association of Scientific Workers. Lord Rutherford of Nelson was born on August 30, 1871, at Brightwater, near Nelson, in New Zealand. He was a student at Canterbury University College and graduated M.A. in 1893 with double first-class honours. He was awarded an 1851 Exhibition science scholarship in 1895, and he left New Zealand to study in Cambridge under Sir J. J. Thomson. Except for brief visits on official occasions, Rutherford never took up residence again in his native land, although many New Zealand physicists came to Great Britain to study under him. Five of the addresses are by his former students. Rutherford's early life is described by Dr. L. Bastings; his connexion with Canterbury University College by Prof. R. S. Allan, now professor and formerly lecturer in geology at the College; and the period spent by Rutherford at McGill University and the University of Manchester by Prof. D. C. H. Florance, who worked with Rutherford at Manchester at the time when the latter was formulating his theory of atomic structure. Dr. G. T. P. Tarrant, now senior lecturer in physics at Canterbury University College, but who formerly spent eight years at Cambridge, three as undergraduate and five as a research worker directly under Rutherford's guidance, contributes an appreciation of Rutherford and his work while at the Cavendish Laboratory, Cambridge. Dr. E. Marsden, who was associated with Rutherford both as student and colleague, and who has already paid tribute in Great Britain (Rutherford Memorial Lecture of the Physical Society, 1948) to Rutherford's kindness, amiability and greatness, gives an account of him as a man. The sixth address, by Prof. R. R. Nimmo, who recently returned to New Zealand after working for several years at the University of Birmingham on nuclear physics, describes the significance and importance of Rutherford's work in present-day nuclear research. This special issue of the *Review*, illustrated with several interesting photographs which have been made available by Lady Rutherford and which are published for the first time, is a fitting tribute to the great man's memory.

Phytomorphology: a New Botanical Journal

With the appearance of the first numbers of *Phytomorphology*, a new botanical journal makes its appearance. This is the organ of the International Society of Plant Morphologists, founded at a meeting of the Pan-Indian Ocean-Science Congress held in Bangalore, India, in January of the current year. The object of the Society is to promote international co-operation in work on plant morphology, anatomy and embryology in the widest sense. It is hoped that the new journal will appear four times a year after the first year. Prof. P. Maheshwari, of the University of Delhi, is acting as convener of the Society and as editor (with the co-operation of botanists in different parts of the world) until formal elections to the executive council and editorial board can be held in 1952. Already some 290 members had been enrolled by October 1.

The first two numbers of vol. 1 of *Phytomorphology* make a substantial beginning. The papers include some of a specific factual kind and others in which themes of a more general character are discussed. Among the latter may be mentioned "The Use and Abuse of Anatomical Data in the Study of Phylogeny and Classification" (I. W. Bailey), "The Relationship of the Caytoniales" (T. M. Harris), "Organization in Plants" (C. W. Wardlaw), "The Male and Female Gametophytes of Angiosperms—An Interpretation" (E. Battaglia). A considerable paper on "The Leguminous Seed" is contributed by E. J. H. Corner, while A. G. Stokey has dealt in some detail with "The Contribution by the Gametophyte to Classification of the Homosporous Ferns". The journal is printed in a good clear type in double columns. The subscription is £2 10*s*. a year.

Physics in Canada, 1951

A recent publication of the Canadian Association of Physicists, "Physics in Canada, 1951", contains several interesting articles and a valuable factual survey of research in physics in Canadian universities, research foundations and industrial and government laboratories, in addition to a directory of Canadian physicists. The preponderance of nuclear studies over other branches of physics is particularly striking. The director of the computation centre at the McLennan Laboratory of the University of Toronto, Dr. G. C. Gotlieb, in an article entitled "Machines for Thought", discusses the various types of computing machines and indicates their probable development and effects on scientific work. Turning to their effects on society, Dr. Gotlieb examines Wiener's ideas on the subject as stated in the latter's book, "The Human Use of Human Beings", and asserts that Wiener does not make it clear that the Industrial Revolution originates from a deeper source than the development of machines. Cosmic ray research in Canada is reviewed by Dr. D. C. Rose, of the National Research Council, Ottawa, and some trends in modern meteorology by Dr. D. P. McIntyre, of the Meteorological Division of the Department of Transport. "As I recall Rutherford" is the title of a brief article by Dr. O. H. Westcott, associate professor of physics at McGill University, and formerly of the University of Birmingham and the Telecommunications Research Establishment, England. Dr. Westcott, in his appreciation of Rutherford, recalls some of the impressions he gained when a research student at Cambridge in the Cavendish Laboratory during the last four years of Rutherford's directorship of the Laboratory.

Publication of Papers by the Institution of Electrical Engineers

A noteworthy modification in practice in regard to the publication of scientific papers by the Institution of Electrical Engineers was initiated with the issue in October of a new section, Part 4, of the *Proceedings* of the Institution. In this new Part will be published from time to time, and in any case not less often than once a year, papers which are considered to be of so specialized a character as to be essential to the work of only a small minority of the readers of Parts 1, 2 and 3 of the *Proceedings*. The printing of such papers proceeds as soon as possible after their acceptance, and they are made available without delay as separate Institution monographs. The appearance of these is announced in the *Journal* of the Institution and on separate announcement sheets. A further step towards making Institution papers available as early as possible is the provision of early proofs of papers intended for presentation at a meeting of the Institution. Papers accepted for reading have first to take their place in the programme of meetings and may, after being read, have to wait possibly four or five months before being published. These papers are now printed without delay, and proofs are made available as soon as they are ready and are announced along with the monographs. There are, however, no early proofs of papers which have been accepted for publication but are not for reading at a meeting. The price of early proofs is 2*s*. 6*d*. and that of monographs 1*s*. 3*d*., but the early-proof service provides, without further charge, a reprint of the paper together with the report of the discussion on it. To facilitate the purchasing of early proofs, reprints and monographs, books of eight voucher-labels are available at a cost of 10*s*.

Earthquake Activity in New Zealand during 1949

The *Bulletin* of the Dominion Seismological Observatory, Wellington, extracted from the annual report for 1950 of the New Zealand Department of Scientific and Industrial Research, states that in 1949 the greatest number of earthquakes felt in New Zealand occurred during February of that year; and one of the strongest shocks of the year happened on February 10 off the coast of South Taranaki. The highest intensities in this shock affected the Taihape–Wanganui area, and it was perceptible from Tolaga Bay to South Canterbury. A shock of intensity 6 on the Modified Mercalli scale occurred in the southern part of South Island on May 27; and one of intensity 5–6 occurred between Murchison and Hanmer on September 28. On June 27 a shock in the White Island region occurred at a depth of 330 km. Shocks located in unusual regions occurred on April 14 and May 27, some 100–200 miles east of Christchurch, and on September 16 west of Cape Egmont. In all, ninety-seven earthquakes were reported felt during the year: seventy-one in North Island, thirty-four in South Island, and eight in both Islands. By arrangement with the Director of Meteorological Services, records from the Milne–Shaw seismograph at Suva, Fiji, were sent to Wellington for interpretation and publication of readings. Work has also been begun at the Observatory on a series of measurements of wave periods in local earthquakes, recorded at various seismograph stations in New Zealand, to provide some provisional data for the design of earthquake-resistant structures.

Territorial Behaviour in Birds

In some experimental work which involved the movement of nests within and across the boundaries of male territories in a small nesting colony of red-winged blackbirds (*Agelaius phoeniceus*), R. W. Nero and J. T. Emlen, jun., demonstrated certain characteristics of territorial behaviour which had not previously been described (*Condor*, 53, No. 3; May–June 1951). They show that the males recognized sharp and stable territorial boundaries which could be defined within a few feet and that they vigorously defended their territories against the intrusion of alien males, females or fledglings except when the latter were quiet; they also tolerated the introduction of alien nests. The males did not extend their aggressiveness beyond their territory boundaries even in the defence of their mates or nests in neighbouring territories. The females freely followed their nests as they were moved experimentally through the territory of the mate, but assumed a subordinate attitude and followed with difficulty when their nests were transported across territory boundaries; they took no part in the defence of the male territory, but opposed the encroachment of alien females on their nest vicinities. Males eventually accepted alien females which persistently invaded their territories to reach transported nests, while female residents of the same male territory tolerated each other at close quarters after nesting was under way but repulsed actual visits to the nest.

Council for the Promotion of Field Studies: Annual Report for 1950–51

In his annual report for 1950–51 to the Council for the Promotion of Field Studies, the director, Mr. F. H. C. Butler, states that the hope that local authorities would provide grant-aid to students to meet the increased charges recommended by the Ministry of Education has not been realized. This, coupled with the fact that a large number of students are not eligible for grants of any kind, has resulted in a serious decline in the number of students attending three of the Council's centres. At the fourth, Malham Tarn, the support of authorities in the North of England, and of the West Riding of Yorkshire in particular, has led to little decline in bookings. Hitherto, the salaries of scientific staff have been met by a direct grant from the Ministry of Education, and it would appear that the negative practice of providing grant-aid through local authorities is bound to lead to insecurity and lack of confidence among the scientific staff at the centres. The methods of providing grants for the Council should be re-examined, and its needs both as regards capital and maintenance re-assessed with due regard to those problems of conservation and pressure of student population which are particular to the Council's case (see *Nature*, June 30, p. 1041).

The Biology of Hot and Cold Deserts

The Institute of Biology is arranging a three-day conference on "The Biology and Productivity of Hot and Cold Deserts" during September 25–27 at the Royal Institution, London. Speakers from some eight countries have accepted invitations to give papers which will deal with problems of physiology and plant and animal ecology resulting from particular geographical conditions. Further particulars will be available in due course from the Institute of Biology, Tavistock House South, Tavistock Square, London, W.C.1.

University of Glasgow

The following lecturers have been appointed in the University of Glasgow: A. W. Babister (aeronautical engineering), S. A. Barrett (zoology), E. H. Bellamy, W. K. Burton, A. L. Cockroft and J. G. Rutherglen (natural philosophy), W. A. Donaldson, J. Hunter and A. P. Robertson (mathematics), A. B. Garven and J. E. Gibson (civil engineering), J. S. S. Inglis (animal husbandry), S. Jennings (veterinary surgery), J. Loudon (engineering production), I. M. McIntyre (veterinary medicine and surgery), H. A. Moisley (geography), W. Mulligan (veterinary biochemistry), and R. S. Patrick (pathology). R. Ogilvie MacKenna has been made librarian and keeper of the Hunterian Books and MSS. Group-Captain W. K. Stewart has been appointed honorary lecturer in aviation physiology. John B. Birks has resigned from a lectureship in natural philosophy to become professor of physics in Rhodes University, Grahamstown. For the present session, new admissions to the Science Faculty of the University amount to 232, compared with 250 a year ago; and there are about two hundred research students. Over all departments of the University, the total number of matriculated students is now about 6,500 (5,150 men and 1,350 women).

Announcements

The annual meeting of the Science Masters' Association will be held in the University of Liverpool during January 2–5, under the presidency of Dr. J. F. Mountford, vice-chancellor of the University. Particulars can be obtained from W. G. Rhodes (Annual Meeting Secretary), 318 Granville Road, Sheffield 2.

The Mathematical Association is holding its annual meeting during January 3–4 at the Polytechnic, Regent Street, London, W.1. Particulars can be obtained from F. W. Kellaway, 87 Pixmore Way, Letchworth, Herts, or Miss W. A. Cooke, High School, Slough, Bucks.

THE STEPHENSON BUILDING, KING'S COLLEGE, NEWCASTLE UPON TYNE

ONE of the most difficult problems of the older civic universities is that of finding room for the expansion necessitated by the large increase in the number of students and the widening scope of university studies. In Newcastle upon Tyne, King's College (the Newcastle Division of the University of Durham) lies near the centre of the city, and the civic authorities, conscious of the value of the College to the city and much impressed by its development in recent years under the guidance of Lord Eustace Percy as Rector, have been of great assistance in making possible the expansion of the College in its present locality. It is thanks to their co-operation, and that of the freemen of the city, that an island site very near the old College has recently been made available for the erection of a new building for the Department of Mechanical and Marine Engineering, with its allied branches of Chemical Engineering, Production Engineering, Fuel Technology and Agricultural Engineering.

This is the Stephenson Building, formally opened on November 28 by H.R.H. The Duke of Edinburgh, who explained in his speech that the building is named after George and Robert Stephenson, the father and son who did so much to develop mechanical engineering. George Stephenson lived for a time within a stone's throw of the site, and it is a matter for congratulation that the Department now possesses his portrait, recently presented to King's College by Dr. S. F. Dorey, president of the Institution of Mechanical Engineers during 1950–51, and a former student of the College. It is a copy of the Lucas portrait painted in 1847 when George Stephenson was the first president of the Institution of Mechanical Engineers.

The Stephenson Building has been designed for the study and teaching of mechanical and marine engineering, and its allied branches. It will accommodate 650 students in all.

The Department is well known for its courses in marine engineering—only three British universities offer such a course. Of recent years, increasing numbers of students from all parts of the world go to Newcastle, not only to attend the University course, but also to take advantage of the opportunity to visit local industries and works concerned with marine engineering and shipbuilding. Apart from the specialized courses, of which marine engineering is only one, students from other branches of engineering and applied science attend the Department of Mechanical Engineering for part of their studies. Other buildings in the College are available for specialized instruction in electrical engineering, civil engineering, metallurgy, naval architecture and mining.

In the Stephenson Building there is 70,000 sq. ft. of working floor space under cover, and half of this is on the ground floor. There is in addition an enclosed courtyard. To make the best use of the site an extra 10,000 sq. ft. of floor space has been added by building an additional storey on the front part of the building. For the time being, the additional floor is being used to accommodate the Department of Mathematics, and the proximity of the Engineering and Mathematics Departments is expected to be to their mutual advantage.

Where very large rooms were required, for example, for laboratories for strength of materials, hydraulics, heat engines, chemical engineering and workshop, goods entrances have been provided directly into each laboratory, and overhead travelling cranes of 5 tons capacity have been installed. Service ducts are provided underground to supply electricity, water, gas and steam to any point required on the ground floor.

The laboratories have been designed so that changes can be made there as easily as possible. For example, there are test points in the walls for tapping off a substantial electricity supply for experimental work; there are grillages in the floor to which apparatus and machined cast-iron blocks may be fixed whenever required. Concrete foundations for machinery have been used only when there was no other alternative. Service pipes have been fixed in many of the laboratories high up on the walls, so as to make access easy for connexions and alterations. Classrooms and lecture theatres have been located in the upper storeys, away from the noise of the laboratories and workshops. A noteworthy feature is the large number of small rooms used for study rooms, classrooms, offices, stores and research rooms. There are more than a hundred of these small rooms in the Stephenson Building, taking up nearly 40 per cent of the total working floor space.

Private rooms for the teaching staff have been placed as near to the laboratories and workshops as possible. This has been achieved by arranging them on a gallery around the periphery of the laboratories, which has the advantage that it provides for observation and supervision of the laboratories without perambulation. In the main block there is a single entrance for students and visitors, so that the laboratories are not used as corridors.

A larger proportion of the resources available than is usual has been spent on workshop facilities. Prof. A. F. Burstall considers that a high-grade workshop equipped with up-to-date machine tools and measuring equipment is the first essential for a department of mechanical engineering, for the dual purpose of making apparatus for the whole Department (and for other departments of the College) and serving as an experimental laboratory for the course that has recently been started in production engineering. This workshop is particularly useful for making special apparatus for students' projects, which are specific tasks allotted to honours and postgraduate students and requiring the design and manufacture of a piece of equipment as part of the student's training. Apart from its value for this purpose, it has been found a useful way of adding to the Department's store of apparatus and special equipment.

At a Congregation of the University of Durham held in the building before the opening ceremony, the honorary degree of doctor of civil law was conferred by the Vice-Chancellor on the Duke of Edinburgh. In declaring the building open, the Duke said that two great wars had destroyed the prosperity which the Stephensons helped to create; it is now the task of universities and technical colleges to train and develop the minds of men who may one day be the means of restoring that prosperity. Engineers and men of science must produce new ideas and improved ways of supplying the world's demands. Prof. A. F. Burstall, head of the Department of Mechanical and Marine Engineering, in thanking the Duke for opening the building, said he hoped that the work done there would justify the faith of the University Grants Committee and the generosity of the Government.

PURIFICATION OF THE CELLULASE OF *MYROTHECIUM VERRUCARIA*

By D. R. WHITAKER

Division of Applied Biology, National Research Laboratories, Ottawa

SINCE the early work of Pringsheim, a multi-enzyme system has been repeatedly postulated to explain the enzymatic breakdown of cellulose to glucose[1,2]. The evidence for this mechanism is largely indirect and, so far as I know, no extensive concentration or purification of any enzyme component has been reported. The need for more direct evidence prompts this communication on procedures for the concentration and purification of the cellulase in culture filtrates of *Myrothecium verrucaria* Alb. et Schw., strain *USDA* 1334.2. Many of the cellulolytic properties of this culture filtrate have been described by Saunders *et al.*[3].

The mould was grown in a medium of 0·1 per cent glucose, 3 per cent benzene-alcohol extracted, ground cotton linters, and mineral salts of essentially the same composition as given by Saunders *et al.*[3]. No glucose was included in the medium for the shake-culture inocula. After nine to twelve days incubation at 30° C., with continuous aeration and rotary shaking, the medium was filtered, chilled to 1° C. and cleared in a Sharples super-centrifuge.

Enzyme activity was assayed by the increase in the Somogyi reducing-sugar titre given by the enzyme after 17 hr. at 35° C. in a shaken 1 per cent dispersion of precipitated cellulose in 0·05 *M* acetate buffer of *p*H 5·6. Thymol was present as an antiseptic. The precipitated cellulose was prepared from non-absorbent cotton by the method of Scales[4], followed by dialysis, precipitation and washing with ethanol, and vacuum drying. The relationship between the concentration of enzyme preparation and the reducing-sugar titre was approximately linear at low enzyme concentrations. The assay standard was taken as 0·5 ml. of untreated culture filtrate in 20 ml. of assay medium, and more concentrated solutions were assayed at dilutions giving approximately the same assay as the standard.

The culture filtrate was concentrated in 30-litre batches to about 8 litres by two passages at 30° C. through a Bartholomew evaporator[5], and then to about 3 litres by slow freezing at − 12° C. in an insulated glass jar, the ice being removed in a basket centrifuge. This concentration caused little loss in activity. The concentrate was cleared in a high-speed centrifuge and fractionated at *p*H 7 with ammonium sulphate; the precipitate forming at between 30 per cent and approximately 95 per cent saturation contained most of the activity. It was centrifuged to minimal volume, extracted by shaking with 200 ml. of distilled water for 6 hr. at 1° C., and the extract cleared by centrifuge. A typical extract, with a protein content of 2·6 per cent, had approximately a hundred times the activity of the original culture filtrate. There was no appreciable loss in activity on freeze-drying or on dialysis against dilute phosphate buffer with gold-beater's skin membranes. In the ultracentrifuge, the extract showed only one peak at *p*H 6·8, but this spread rather rapidly, suggesting polydispersity (Fig. *A*1). Electrophoresis at *p*H 6·8 showed at least four components (Fig. *A*2).

This extract could be purified chromatographically on calcium phosphate gel columns by the method of Swingle and Tiselius[6]. The most active fraction was

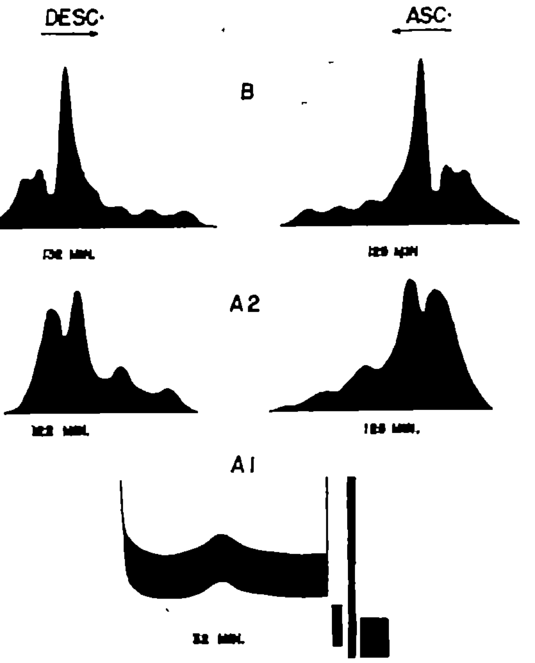

Fig. *A*1. First extract. Protein concentration 0·61 per cent, *p*H 6·8, *μ* 0·2. Speed, 60,000 r.p.m.
Fig. *A*2. First extract. Protein concentration 0·61 per cent, *p*H 6·8, *μ* 0·2
Fig. *B*. Fraction 2. Protein concentration 0·66 per cent, *p*H 6·8, *μ* 0·2

obtained by adsorption at 1 per cent protein concentration in 0·001 *M* KH_2PO_4,Na_2HPO_4 at 1° C., and elution with 0·05 *M* KH_2PO_4,Na_2HPO_4. Its activity per unit protein concentration was approximately double that of the extract. The main change in the electrophoretic pattern was a marked reduction of the slowest-moving component, and, in addition, a further minor fast-moving component could be resolved. Total recoveries from the columns were low, there being a marked tailing effect on elution.

A simpler fractionation is by ammonium sulphate precipitation in 2*N* acetate buffer of *p*H 5·6. On a 1 per cent protein solution, pooled from the most active chromatographed fractions, fraction 1 (precipitated at 50 per cent saturation) contained 23 per cent of the total protein and 18 per cent of the total activity towards precipitated cellulose. Its electrophoretic pattern showed marked enrichment in the fastest- and the slowest-moving components. Fraction 2 (precipitated at 100 per cent saturation) contained 72 per cent of the protein and 81 per cent of the activity. Its electrophoretic pattern (Fig. *B*) showed appreciable enrichment in the main intermediate component and appreciable loss in the fastest and slowest ones.

The enrichment of fraction 2 in activity towards precipitated cellulose was accompanied by enrichment in activity towards cellobiose and towards linters swollen in alkali by the method of Jørgensen , a swelling treatment claimed to cause only a conversion of crystalline to amorphous cellulose. Assays with swollen linters gave a somewhat higher value (c. 85 per cent) for the total activity in fraction 2. Assays with cellobiose gave results that depended on the concentration of cellobiose, hydrolysis appearing to be inhibited at higher concentrations. However, at all concentrations tested, from 0·1 to 1 per cent cellobiose, fraction 2 had the highest activity.

The rate of enzymatic hydrolysis varied greatly with the substrate, the following data for fraction 2 being typical :

0·1 per cent cellobiose, 0·0025 per cent protein :	54 per cent hydrolysis in 17 hr.
1 per cent precipitated cellulose, 0·0003 per cent protein :	12 ,, ,, ,, ,, ,,
1 per cent swollen linters, 0·0006 per cent protein :	5·2 ,, ,, ,, ,, ,,
1 per cent ground linters, 0·006 per cent protein :	1·2 ,, ,, ,, 40 ,,

The percentage hydrolyses for the celluloses were calculated by converting reducing-sugar titres to glucose and are thus minimal. Untreated linters was thus very slowly attacked. The importance of its crystallinity in this respect has been stressed by Pigman[8].

I am indebted to Dr. W. H. Cook and Dr. J. R. Colvin of this Division for the ultracentrifugal and electrophoretic examinations. [July 12.

WORLD CONFERENCE ON DOCUMENTATION

THE eighteenth Conference of the International Federation for Documentation was held in Rome during September 15–21, under the auspices of the Consiglio Nazionale delle Ricerche.

More than three hundred participants, representing thirty-one countries and a few supra-national bodies, including the Organization for European Economic Co-operation, Unesco and the Food and Agriculture Organization, took part in the proceedings, which were inaugurated by an official ceremony at the Capitol. The entire Conference was housed in the building of the Consiglio Nazionale delle Ricerche, Piazzale delle Scienze, in front of the Città Universitaria.

More than one hundred papers had been prepared, and, with most of them printed and some duplicated, they filled four bulky volumes which take a few weeks to study. To facilitate reference, not only for the future, but also, mainly, for purposes of the Conference, these papers have been listed in two ways : by country and subject. It is thus possible to gain an overall picture of achievements, ideas, suggestions in a particular country, or study developments, trends and openings in any specialized field. The listing by subject followed closely the grouping adhered to in the Conference programme as follows : (1) application of the Universal Decimal Classification ; (2) documentary reproduction methods and mechanical selection devices ; (3) bibliography and abstracting ; (4) auxiliary publications ; (5) training of documentalists ; (6) general problems of classification ; (7) linguistic problems and terminology.

It was unfortunate that only a few delegates had received their papers in time to allow preparatory study. For technical reasons, outside the control of the organizers, the rest became available for distribution only after the proceedings had started.

It would require a separate article to assess the encyclopædic value of these papers, record their contributions to routine, point to new problems which are raised and new approaches which are suggested. The present review must limit itself to the Conference and its outcome.

The main topics discussed by the various sections may be briefly described by abbreviated versions of the recommendations. The recommendation of Section (1) refers to the question of authorities responsible for publicizing and explaining the principles and practice of the Universal Decimal Classification. Among the specific tasks recommended for immediate attention, the following are especially mentioned: compiling and circulating a list of Universal Decimal Classification users; securing distribution of the new cumulative Extensions and Corrections to the Universal Decimal Classification; preparing a short edition based on the latest available Dutch "Verkorte Uitgave"; assisting in the revision of specific Universal Decimal Classification sections with special reference to the preparation of the fourth (English) and fifth (French) editions; preventing the distribution of unauthorized editions. Multilingual editions were also recommended by the Section.

The deliberations of Section (2) were centred on the comparative merits of the different micro-techniques, and the recommendations limited to matters of format and terminology. Questions of method and policy, touched upon in some of the printed papers, did not come up for discussion. Some of the delegates found fault with the exhibition of technical devices, organized for the Conference at the Istituto di Matematica, because it did not offer the ultimate solution of their problems. While the scope of the exhibition did not differ greatly from similar shows previously displayed in Britain or elsewhere, attention might be directed to a series of microcard readers, at different price-levels, from the United States, and to a prototype of a simple camera of Italian make for taking flat micro-film of the 'fiche' or sheet type. This type of film, incidentally, is gaining popularity (as might have been foreseen) for purposes where convenience of handling, filing, and so on, are more important than speed of initial operation.

Section (3) emphasized the need for better dissemination of technical information contained in patent specifications, recommended the drafting of standards for citations and descriptions of references, and discussed the possibility of standardizing the bibliographical and formal presentation of abstracts.

The discussions of Section (4) resulted in a recommendation urging universities and scientific institutions to have academic writings which they deem important published or reproduced by an appropriate process in numbers sufficient for the needs of exchange purposes, and noting, further, that such exchanges should not be based on the monetary value of the document. The Section also suggested that other scholarly production existing only in manuscript form should be listed in analytical bibliographies with indication of the depository library or documentation centre able to supply copies upon demand.

Much thought was devoted by Section (5) to the problem of training documentalists. It was, *inter alia*, suggested that archives and museums should be invited to participate in the deliberations hitherto attended mainly by librarians; that professional education should be regionalized wherever such development might be considered useful; that prototype programmes of education in documentation should be discussed in 1952, and a conference of persons responsible for the training of librarians and documentalists should be convened for 1953. It was finally suggested that, in response to an international need, documentation should be recognized as a profession in its own right, and that a professional statute for documentalists should be drawn up.

Section (6) recommended a survey of the different systems of classification now used in libraries, archives, documentation centres and government offices, and expressed the hope that possibilities of co-ordinating the different systems might be explored.

The recommendations of Section (7), worked out in considerable detail, may be summarized as follows. The specialized dictionaries hitherto available cover no more than a small part of all technical subjects and languages. Most of these dictionaries are technically inadequate from the user's point of view. Production of specialized vocabularies should be organized on international and national levels, and should be preceded by preparatory tasks under these headings: standardization of terminological and lexicographical principles; compilation of terminological bibliographies and directories of organizations dealing with terminological questions; compilation of bibliographies of classifications and of directories of organizations dealing with classifications. The various tasks should be assigned to specialized agencies, and only the international co-ordination should remain centralized.

The full text of the recommendations—of which only the gist could be given here—was formally adopted by the plenary session and submitted to the Council of the International Federation of Documentation, of which M. Arne Møller (Denmark) is now president.

The working programme of the Conference was pleasantly interrupted by a number of social engagements. A special and unexpected event was the audience granted to the participants of the Conference by the Pope at the Palazzo Pontificio di Castel Gandolfo, the Pope's private residence in the Alban Hills. His speech, in French, in which he summed up the problems confronting documentation, was afterwards published in the *Osservatore Romano* on September 21.

LUCIA MOHOLY

STATISTICAL METHODS IN CHEMISTRY

ON October 25, the London and South Eastern Counties Section of the Royal Institute of Chemistry held a discussion on "The Application of Statistical Methods to Chemistry". This was planned as a supplement to the course of lectures on statistical methods given for the Institute by Mr. D. R. Read in September 1950. Under the chairmanship of Dr. C. W. Herd, more than two hundred members assembled to hear four speakers give prepared answers to questions that had been submitted and to inquire for further information on special points.

In the first of the four short papers, Dr. E. C. Wood described how careful attention to experimental design can benefit the chemist. He emphasized particularly the difference between the 'classical' approach of testing each relevant factor in turn, in order to assess its effect on a quantity to be determined, and the modern method of factorial design. He showed that, when the best value for one factor in a chemical reaction depends upon the level of others, the classical method might fail to discover the optimal conditions in respect of the several factors. The alternative of testing a carefully selected set of combinations of levels of all the important factors may give more information on the optimal, from a smaller total number of observations yet with increased assurance that relevant interactions of factors had not been overlooked. Dr. O. L. Davies supplemented Dr. Wood's remarks by illustrating how, when tests of combinations of factors are to be made in succession rather than simultaneously, recent developments of special designs in the 'steepest ascent' technique can be made to yield information on the optimal even more economically. Dr. D. J. Finney later directed attention to the importance of randomization and the true independence of replicate observations in order that valid assessments of experimental error might be made.

In the second paper, Dr. D. J. Finney was concerned with the problem of choosing a form of curve to represent experimental data. He said that if mathematical theory can suggest the appropriate type of curve, this should be used and statistical theory would then show how to estimate it. If not, the experimenter should ask himself whether he really wants a curve, and should not try to fit one unnecessarily. Various transformations might be tried in order to bring a freehand curve into approximately linear form; but data additional to the first experiment would be needed in order to estimate the relationship as well as to infer its form. For smoothing and interpolation, as distinct from study of the fundamental relationship, the precise form of curve is often unimportant, as, for example, in bioassay. He warned particularly against extrapolation and against confusion of purpose between a 'utilitarian' curve and one representing fundamental properties of the material. Mr. D. R. Read illustrated the occasional need for fitting a complicated curve.

Dr. Davies had been asked to discuss a particular question relating to the sampling of tablets required to conform to a specification of density. He spoke of the need for care in the selection of a representative sample from each batch of tablets. This sample must be large enough to give reasonable confidence that a bad batch will not be accepted as good, nor will a good batch be rejected as bad on account of sampling variations. He gave details of two statistical tests, both sequential. The first involves classification of a random succession of tablets as 'good' or 'bad' until evidence on the proportion of good ones enables a decision to be taken. The second, using a sequential t-test, requires measurement of the density of each tablet instead of mere classification, but on an average would permit a decision to be reached from examination of about half as many tablets; the choice between the two methods must depend upon the relative costs of classifying a tablet as good or bad and measuring its density. For either test, the tablets in the whole sample selected must be examined in random order. Dr. Wood mentioned the dangers of uncritical use of sequential sampling.

Mr. Read's paper related to the rejection of apparently anomalous outlying members of a series of chemical determinations. He said that, though some discrepant observations might justifiably be rejected because of known accidents or anomalies during the experiments that produce them, the chief difficulty relates to whether (and when) observations might be rejected purely on the internal evidence that they had been affected by exceptionally large 'random' errors. He held that even in these circumstances an observation may occasionally be legitimately rejected, in the light of common sense, knowledge of relevant circumstances, and demonstration that its value is almost certainly too discrepant to be due to chance. He presented several statistical tests recently proposed for assessing the evidence for significant aberrancy in outliers, and suggested comparing their merits in terms of the probabilities that they would discover the contamination of a set of observations by an accidental error of specified size. He considered that one or other of these tests might be of real practical value, but that neither should be uncritically adopted. Dr. Finney and Dr. Wood later expressed doubts about the general utility of statistical tests for making what is basically a moral decision: whether or not to regard a particular observation as the product of accident, incompetence, or lunacy (rather than as a fair representation of natural deviation from a norm), on the sole basis of the internal evidence of the data. Dr. Wood nevertheless advised that long experience of the type of variation normally encountered with certain material might justify the experimenter in attributing an occasional aberrant value to an unsuspected accident.

The chairman then reviewed the papers. Before opening the meeting to general discussion, he commented on two matters: the frequent need for a decision, at one moment of time, on the sampling procedure for a bulk of material (such as a consignment of iron ore) that would thereafter not be available for further study, and the permissibility of rejecting a measurement about the validity of which an expert analyst is suspicious even though he cannot assign a reason. In reply, Dr. Davies emphasized the need for treating every sampling problem on its merits, in the light of knowledge of the material and its variability; the statistician could not devise a good scheme without preliminary study, possibly based upon a pilot sample. Mr. Read pointed out that only the experimenter could decide whether his 'hunch' justified him in rejecting the observation immediately or in making further experiments and applying a statistical test for rejection.

The questions and discussion that followed were of great interest, but can be reported only briefly. Many raised further points about the rejection of outliers. Mr. A. L. Bacharach pointed out that Dr. Wood's suggestion of deciding on rejection from past experience of the reasonable variation in the material under test is essentially an appeal to a statistical criterion (or else a doctrine of expediency). Dr. Finney suggested that control charts might be adapted to the evaluation of past experience in relation to rejection, and Mr. Sears said that the Institute of Petroleum has recommended something of this kind. Mr. Battersby mentioned that, in the analysis of bauxite, if two different analyses are seriously discrepant, it is customary to make several additional analyses and to average all results without rejection. Mr. Haslam spoke of the need for checking the effect of the personal factor, by making analyses or other measurements on material the true nature of which is known to others but not to oneself. Mr. Stevens commented on the danger of a spurious appearance of precision when publication of an analytical process in a standard work of reference is based upon multiple analyses in one laboratory: other workers, whose laboratories are possibly less exactly controlled, may show much poorer agreement through no fault of their own. Dr. Davies agreed that different laboratories often show appreciable differences in standard analyses. Dr. Finney emphasized the need for remembering that any standard deviation relates to the variation from a particular set of causes, and may well fail to characterize the dispersion of actual observations when additional sources of variation are introduced. Mr. Bacharach argued strongly that new standard analytical techniques ought to be studied collaboratively in several laboratories; he also reminded the audience that outliers should never be rejected without examination of causes, for observations that were apparently anomalous have often been the start of great new developments. Mr. Smart quoted an instance of a set of two hundred observations that conformed excellently to a normal (Gaussian) distribution if six extreme values were rejected; Dr. Finney maintained that this in itself did not justify the rejection unless there were strong *a priori* reasons for believing that the true distribution was normal.

Mr. Senior asked for advice on the sampling of very valuable material, for which the actual cost of the portion used in analysing a sample might be important. Dr. Davies suggested that the difficulty could be removed by the chemist devising techniques for the analysis of very small quantities. Dr. Wood pointed out that the policy to be adopted must be determined on economic grounds: if decisions of great monetary or other importance depend upon reliable analytical information, even large expenditure on sampling may be a desirable measure of insurance against grave errors.

Several other inquiries related to the sampling of continuous processes. Mr. Hewitt asked about the frequency with which indicators of a process ought to be read in order to provide adequate evidence of whether or not the process is in control. Mr. Soper suggested standard quality-control practices of intensifying observations when the control is under suspicion. Dr. Davies said that observations must be frequent enough to detect fluctuations of a size that would be important to the process, and that only by knowledge of the process could any more exact guidance be given. Dr. Wood warned against dependence on observations at regular intervals of time, regular in relation to shifts, or in any other way likely to be related to periodicities in the process, since periodic changes might impair the validity of estimates of variability; Dr. Finney directed attention to the non-independence of successive observations on a continuous process and the possibly autoregressive character of the errors.

In reply to a question from Mr. Berkovitch about the number of levels of various factors to be used in a factorial experiment for the estimation of optimal conditions, Dr. Wood suggested that three or four levels of each factor usually suffice. Dr. Finney thought that many factors at two levels each might be used in a preliminary trial, and those that were found most important might later be tested more intensively, at three or four levels each, over a narrower range. Dr. Davies again emphasized the great advantages of a sequential steepest-ascent investigation where this is practicable. Mr. Berkovitch also suggested that extrapolation from a set of observations, in spite of its logical and theoretical flaws, may legitimately be used to indicate useful lines for further experimentation; Dr. Finney fully agreed that this is valuable and certainly permissible provided that the extrapolations are not regarded as established before experiment has confirmed or refuted them. Mr. Soper suggested that time ought often to be regarded as a factor in an investigation, and all experiments repeated at two or three distinct times, since extrapolation in time is essential to the usefulness of any inferences drawn.

D. J. Finney

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING, SHINFIELD

REPORT FOR 1950

The farm must obviously be the site of much of the experimental work of a research organization such as the National Institute for Research in Dairying, Shinfield, and in the annual report for 1950, which has recently been published*, it is made clear that the farm is the important background of much of the laboratory work. The Institute has two farms, covering about seven hundred acres, with more than two hundred head of cattle—largely Shorthorns but with some Friesians and Guernseys. As in many other agricultural research centres, some developments, particularly those involving buildings, are unavoidably slow, and preparation for them occupies a lot of the time of the staff. But within these limits the work of the farms is very progressive, including the implementing of a well-defined breeding programme and the careful cataloguing of all records that may conceivably be needed in the interpretation of experimental results.

Besides maintaining the essential work and records of the farms as such, the Dairy Husbandry Section has a good deal of experimental work to its credit, including a continuation of studies of the rates of milking, of the suitability of certain fodder crops for milk production, and various experiments on the rate of growth and milk yields of pigs.

For some years the Institute has been concerned with factors affecting the efficiency of the use of food by ruminants, and the experimental work has lately been much facilitated by the design of a harness for the satisfactory separation of the urine and the fæces of the dairy cow. Much of this work has since been published. In the recent work it has been found that the softening of finely divided hay (as opposed to long hay) by grinding in the mouth reduces the ability to regurgitate. Initiation of the regurgitation reflex has, however, sometimes been brought about by appropriate hand-scratching.

It has been found that diets low in roughage cause a reduction in fat yield but do not affect the percentage of non-fatty solids. The properties of butter were affected, too, by low roughage diets, the butter having a higher percentage of unsaturated acids and a low softening point.

The report for last year called in question the use of lignin as a 'reference' substance in studying rates of digestion. The validity of using lignin depends on the assumption that it is not digested; but recent work at the Institute has shown that the results of the estimation of lignin digestion can differ considerably according to the method used, and also by the same method according to differences in composition of the diet. The lignin ratio technique is therefore suspect.

---

* University of Reading: National Institute for Research in Dairying. Report for 1950. Pp. 103. (Shinfield: National Institute for Research in Dairying, 1951.) 2s.

The important work following the recent demonstration of œstrogen in British pasture is continuing in conjunction with the Courtauld Institute of the Middlesex Hospital. While œstrogenic activity was marked in grasses in 1949, there was little in 1950, and attention has been given to broad red clover, the œstrogen content of which seems to be more consistent. The work has been largely directed to the identification and separation of the active substances and to their occurrence, distribution and physiological action. Isolation is proving a difficult problem, but work is being pursued with a good hope that œstrogenic substances will be identified without isolation by a radioactive isotope method.

Work continues on the effects of different levels of œstrogen on mammary growth-rates in rats. American work having shown that a deficiency of folic acid restricts the effects of œstrogen in growth-rates in other connexions, the effect of administering a folic acid antagonist is being investigated in this work. While it is well established that aminopterin has a pronounced effect on body growth in general, nothing specific to mammary growth has yet been found.

The continued study of the synthesis of the fatty acids of milk from acetate (using sodium acetate with radioactive carbon in the carboxyl group) gives further evidence of the view that short-chain acids are intermediate in the formation of long-chain acids from acetate and emphasizes the importance of fatty-acid synthesis in the udder from small molecules. The belief that the utilization of acetate for milk fat synthesis takes place in the udder itself has been substantiated by experiments in which reactions in the liver and elsewhere were excluded.

Bacteriological work is involved in a large number of investigations, and the bacteriological examination of the milk produced on the farm has been systematically carried out. The Institute has co-operated in the work of a committee appointed by the Ministry of Agriculture to examine the resazurin and methylene blue tests, and investigations have been carried out into faults in cream and sterilized milk. The study of the classification of streptococci and lactobacilli continues to occupy several members of the staff. Work on the problem of fat absorption by the cup liners of milking machines, referred to in a previous report, has been finished, and the incorporation into the linings of a proportion of synthetic fat-resistant rubber has been shown to be possible.

Some interesting work is in progress on the role of micro-organisms in the synthesis of B vitamins in the rumen. Straw pulp, alkali-treated straw, hay and concentrates showed, in the order named, decreasing amounts of vitamin complex synthetized and a correlated decrease in the number of micro-organisms in the rumen fluid and on the food.

There is a good deal of work on the effects of antibiotics. The effects of certain antibiotics in accelerating growth in normal chicks have been confirmed. With chicks deficient in animal protein factor, however, this stimulation only occurred with vitamin B_{12}, which can presumably replace the other components of the animal protein factor. In work on the production of antibiotics, no streptococci outside the lactic group have yet been found with antibiotic-producing power.

Study of the physical properties of cheese has suggested some practical tests for quality assessment. The physical and rheological properties of butter have been claiming attention, but the work has not yet reached a stage for report.

The proteins of milk are the subject of a number of investigations. Work connected with the inactivation of lysine during the storage of dried skim milk gives support to the view that lysine is not essential for maintenance in rats. The preheating of milk under pressure before spray-drying did not seem to affect either the biological value or the digestibility of the protein. There is evidence that vitamin B_{12} is involved in protein metabolism: the biological value of casein fed to chicks without B_{12} was 82·2; with vitamin B_{12} it was 89·7.

The testing of all kinds of equipment is a continual concern of the Engineering Department. The work there, however, is not confined to routine; it includes studies of the electronic treatment of milk and of boiler water and the ultra-violet irradiation of milk. In much of this work the staff are in close contact with workers in other countries.

Reference can only be made in this short account to some of the work being done; but these references will show the kind and the diversity of the work, and a catalogue of it can be seen in the list of ninety-five publications appended to the report.

MELLON INSTITUTE, PITTSBURGH

ANNUAL REPORT FOR 1950-51

THE thirty-eighth annual report of the president of the Mellon Institute, Dr. E. R. Weidlein, to the board of trustees, published under the title "Current Scientific Researches in Mellon Institute, 1950–51"*, covers the year ended February 28, 1951. During this year the Institute's building was completed, including new executive offices, a new periodical room for the library and a new conference room.

In the Department of Chemical Physics a collaborative programme on the properties of synthetic rubber, initiated under the ægis of Multiple Fellowships, designed to study the infra-red spectra of rubber-like polymers, has already shown that sometimes both *cis*- and *trans*-polyisoprenes are produced by the same biological plant. A special Weissenberg camera and a Laue camera have been designed and built for the crystal study at temperatures down to that of liquid nitrogen of compounds normally liquid or gaseous at room temperature. Research in physical chemistry has been principally in the theory of distillation, including a completed study of the performance of intermittent take-off heads for distillation columns. In the Department of Organic Chemistry work has persisted on diabetes caused by alloxan, and work on the biochemistry of mental diseases has tentatively confirmed the hypothesis that the urine (and, presumably, the blood) of some patients contains a pathological constituent, suggesting that the patients also suffer a metabolic or endocrine disturbance. Two series of pteridine derivatives were in the course of being studied—one related to folic acid, and the other to the antagonist, aminopterin. The fellowships which began in 1950–51 have been for research on artists' materials, the technology of furfuraldehyde, matches, meters, and nitrogen compounds, and a comprehensive programme on special fibres. Fellowships completed during the year dealt with the processing of fibres for felt hats, the neutralization of acid mine drainage, the properties of silica gel and the related oxides and the influence of methods of preparation on properties, catalysts for butadiene and synthetic rubbers, the preparation of collapsible tubes from plastics, and the dimensional stabilization of wood by impregnation with a phenolic resin or other chemicals.

---

* Current Scientific Researches in Mellon Institute, 1950–1951: the Thirty-eighth Annual Report of the President, E. R. Weidlein, to the Board of Trustees of the Institute for the Fiscal Year ended February 28, 1951. Pp. iv+52. (Pittsburgh, Pa.: Mellon Institute, 1951.)

The bulk of this report is concerned with research under continuing fellowships, and of these it is only possible to mention but a few to illustrate the wide range of activities at the Institute. Under the Optical Glass Fellowship the variations in physical properties with heat treatment are being investigated, while during the fifteenth year of the Mineral Products Fellowship four products from siliceous wastes from plate-glass plants have been derived. The Ceramic Chemicals Fellowship has been extended to studies of the fundamental reactions of vitreous enamels and to the formulation of compositions yielding enamels which mature at relatively low temperatures and which can be fired at higher temperatures without change in opacity or colour and are highly resistant to acid. Work under the Multiple Fellowship on Acid Recovery has been directed to simplifying a process for the recovery of manganese from low-grade ores with waste pickle liquor, and under that on Chemical Storage a report has been made on the proper storage of forty-four different substances, and also on evaluating the stresses in large tubular elevated water-tank columns. A similar Fellowship on Insulation and Roofing has provided technical information on a new 'Super-Light' 85 per cent magnesia insulation and the development of a new high-temperature insulating material, 'Tempchek'. The Fine Wire and Flat Strip Fellowship has been turned to the production of fine flat-strip for use in such end-products as razor blades, clock and watch springs, pen points and umbrella ribs.

Under the Multiple Fellowship on Nickel a study has been made on several supported nickel sulphide catalysts in the hydrocarbon–steam reaction in the presence of sulphur compounds. The report reviews briefly the twenty years of work under the Multiple Fellowship on Sulphur; the causes, prevention and control of bituminous coal-waste fires were being investigated under the Coal Waste Control Fellowship, while under the Fellowship on Tar Constituents new methods have been worked out for the analysis of crude phthalic anhydride, for the determination of thionaphthen in naphthalene and the analysis of commercial divinylbenzene. Research under a Fellowship on Effluents has led to the isolation of strains of micro-organisms which utilize phenol, and has built up their tolerance to a strength which will destroy phenol in concentrations of 500–1,000 p.p.m. in a modified mineral-salts bacteriological medium; under a Fellowship on Aromatic Anhydrides improved catalysts for the manufacture of phthalic anhydride have been developed; and under another on Special Resins a thorough kinetic study has been made of the condensation of resorcinol with formaldehyde in various solvents. The work of a Multiple Fellowship on Petroleum has included the separation and identification of sulphur compounds in crude oils, the deterioration of lubricating oils by oxidation and the study of metallic catalysts for hydrocarbon synthesis from carbon monoxide and hydrogen. A fundamental study has been made of the factors affecting the loss of activity of granular sugar-refining absorbents in service, while the piperonyl insecticides have been proved safe to warm-blooded animals and are being used in liquid insecticide aerosol formulations, and especially for the protection of stored grain.

Under a Silk Fellowship the factors in the throwing operation which may affect the dyeing characteristics of nylon have been investigated as well as new sizing materials available for nylon yarns. Under the Garment Filling Fellowship a new fibre-forming process, by the corrugation of fibrous webs, has given fillers of exceptional resistance to compression, while in research on fillers for sleeping-bags an entirely new process for utilizing chicken feathers has been developed. Further work on the effects of various 'size additives' has been carried out under the Paper Fellowship, and considerable progress has been achieved during the year under a Multiple Fellowship on Synthetic Rubber Properties in techniques for determining molecular structure and for studying physical properties. A detailed examination of the dynamic and creep properties of poly*iso*butylene as a function of frequency and temperature has been completed.

During the year, under the Multiple Fellowship on Organic Synthesis, some 130 new products were made available in research quantities, fifteen new compounds, including substituted glycols and aromatic glycol ethers, were prepared in pilot plant equipment, and the feasibility of solvent recovery with activated carbon was investigated for the new applications. Fundamental studies were made of the utilization of glyoxal for rendering proteins and carbohydrates insoluble, while a study of 'builders' and formulating techniques has promised to yield non-ionic detergents of high scouring-efficiency and adequate foaming-value. Other work has increased the knowledge of the effect of conditions of application on the performance of polyvinylbutyral 'wash primer' coatings, and improvements in the extrusion rheometer have increased its value in predicting the coating properties of dispersion formulations. Lubricants, anti-foaming agents, resins, moulding compounds and laminating materials developed from organo-silicon compounds in twelve years of work under the Fellowship on Technical Glassware are finding increasing application, while a Cork Fellowship has demonstrated the value of synthetic resins, with their superior abrasion and resistance to solvents, as binders for floorings. Under an Orthopedic Appliances Fellowship a special type of knee joint and lock has been developed and adapted for mass production from die stamping, and improvement has been made in the characteristics of the 'Fibreglass'–'Bakelite' low-pressure resin-laminating system, which is being widely used in the brace and limb industry.

The quantitative pharmacology of more than sixty chemicals has been outlined under the Fellowship on Chemical Hygiene, a detailed study made of ten established compounds, and correlations established between frequencies and depths and the retention of inhaled dusts. Field researches have included studies on the chemistry of the oxidation of sulphur dioxide and the development of instruments for measuring the intensity of atmospheric pollution at ground-level, as well as six medical surveys and various studies in industrial hygiene.

ABO Blood Groups and Sex-Ratio at Birth in Man

SEX-RATIO at birth in man and some other organisms has been a subject of investigation for several decades. No clear evidence has been available indicating its association with any known hereditary trait. The purpose of this note is to point out such an association of sex-ratio with *ABO* blood groups in man. The data consist of *ABO* determinations of 1,330 mothers and cord blood of their newborn infants, delivered during the second half of 1944, at the Nowrosjee Wadia Maternity Hospital in Bombay. The original purpose of that investigation was to study the frequency of subgroups of *A* in the sample of mothers[1] and the incidence of hæmolytic anæmias in their newborn infants[2,3]. Recently there was occasion to re-examine the data for *ABO* determinations and sex-ratio in infants. Results of this analysis are given in Table 1.

Table 1. *ABO* BLOOD GROUPS OF INFANTS CLASSIFIED ACCORDING TO SEX AND BLOOD GROUPS OF THEIR MOTHERS (BOMBAY)

Infant		Mother				
Group	Sex	*O*	*A*	*B*	*AB*	Total
O	Male	158	46	53	—	257
	Female	103	42	44	—	189
A	Male	50	108	20	16	194
	Female	55	109	15	16	195
B	Male	45	23	124	25	217
	Female	33	24	91	18	166
AB	Male	—	19	25	14	58
	Female	—	22	21	11	54
Total	Male	253	196	222	55	726
	Female	191	197	171	45	604

In this table, figures in the three classes, namely, *O* infants born to *O* mothers, *A* infants born to *A* mothers, and *B* infants born to *B* mothers, are large enough for further consideration. There is a significant difference ($\chi^2 = 5 \cdot 57$, $P < 0 \cdot 02$) in the sex-ratio (percentage of males) of *O* infants born to *O* mothers ($60 \cdot 5 \pm 3 \cdot 0$) and the sex-ratio of *A* infants born to *A* mothers ($49 \cdot 8 \pm 3 \cdot 4$). The sex-ratio of *B* infants born to *B* mothers ($57 \cdot 7 \pm 3 \cdot 4$) is similar to the sex-ratio of *O* infants born to *O* mothers. The overall sex-ratio is $54 \cdot 6 \pm 1 \cdot 4$.

It was thought necessary to check this finding with data from some independent source. At the Presbyterian Hospital, New York, *ABO* determinations have been made as a routine, mostly of *Rh*-negative mothers and their newborn infants, for the past few years. Analyses of the data collected since January 1949 are given in Table 2.

There is a similar difference ($\chi^2 = 4 \cdot 93$, $P < 0 \cdot 05$) in the New York data to that found in the Bombay data, in the sex-ratio of *O* infants born to *O* mothers ($56 \cdot 3 \pm 3 \cdot 0$) and the sex-ratio of *A* infants born to *A* mothers ($45 \cdot 7 \pm 3 \cdot 7$). The overall sex-ratio in New York data is $52 \cdot 7 \pm 1 \cdot 7$.

It would be difficult to speculate how general is the trend shown in Bombay and New York data. Such a difference could arise by differential mortality during the prenatal period, or differential gametic fertilization or both. Differential mortality, if it exists, would not be explained only in terms of the process of isoimmunization due to *A* and *B* antigens, as the notable differences in the sex-ratio are found in combinations where mother and her newborn infant belong to the *same* *ABO* blood group. A detailed account of this finding with some related evidence will be published elsewhere.

Table 2. *ABO* BLOOD GROUPS OF INFANTS CLASSIFIED ACCORDING TO SEX AND BLOOD GROUPS OF THEIR MOTHERS (NEW YORK)

Infant		Mother				
Group	Sex	*O*	*A*	*B*	*AB*	Total
O	Male	153	45	21	1*	220
	Female	119	54	21	—	194
A	Male	55	85	6	9	155
	Female	51	101	6	3	161
B	Male	21	7	29	7	64
	Female	23	4	15	4	46
AB	Male	—	9	4	4	17
	Female	—	2	4	2	8
Total	Male	229	146	60	21	456
	Female	193	161	46	9	409

* Exception to Bernstein's theory of *ABO* heredity.

I am grateful to Dr. V. R. Khanolkar for technical facilities at the Tata Memorial Hospital, Bombay. I am also grateful to Prof. Leslie C. Dunn, of Columbia University, and Dr. Richard L. Day, of the Presbyterian Hospital, New York, for consultation and encouragement. Information collected at the Presbyterian Hospital by Dr. John L. Scudder was kindly placed at my disposal by Dr. Day.

Discovery of the Expected Hæmagglutinin, Anti-Fy^b

THE hæmagglutinin described in this note was found in the serum of Mrs. Hahn, of Berlin, following the birth of her third child.

The mother gave no history of blood transfusion. Neither her two previous children, nor the third, showed any signs of hæmolytic disease of the newborn, though the first died at the age of two months of a nutritional disorder. She was delivered of her third child, a female, at the Wenckebach Hospital, Berlin Tempelhof, by Dr. Haacke, and the abnormal antibody was discovered two days after delivery in the course of the routine examination of all post-natal maternal sera, carried out at the Robert Koch Institute.

The antibody was found to have a titre of 16,000 when tested against the red cells of both the husband and of the new-born child, suspended in gelatin solution. Against a number of specimens of group *O* cells suspended in saline the titre was 16. The serum was next tested in Berlin against the blood of seven persons whose red cells had previously been tested for nearly all known antigens. The antigen defined by the new antibody was present in six of these bloods, and did not correspond to any for which they had previously been tested. The serum was further tested in London against a larger panel of red cells. It was observed that reactions were stronger in albumin than in saline, and stronger at 37° C. than at room temperature. Again, no correspondence was

THE BLOOD GROUPS OF THE HAHN FAMILY

Initials	Relationship to U. H.	Reaction with serum of U. H.	Fy^a	ABO	Rh	MNS	P	Lu^a	$Kell$	Le^a	Le^b
U. H.	—	−	+	O	R_2r	MMS	+	−	−	−	+
Rg. H.	Husband		+	A_1	R_1R_1	MMS	+	−	−	+	−
A. H.	Second child		+	A_1	R_1r	MMS	+	−	−	−	+
E. B.	Mother	+	+	O	R_1R_2	MNS	+	+	−	−	+

Er H.	Father-in-law	+	−	O	R_1R_1	MNS	−	−	−	−	+

observed with any known antigen; but it was found that all the non-reactors were positive for the Duffy antigen (Fy^a) of Cutbush, Mollison and Parkin[1] and that all the Duffy negatives were positive for the new antigen.

This suggested that Mrs. Hahn's serum contained the expected but hitherto undiscovered antibody anti-Fy^b, reacting with the antigen produced by the gene Fy^b, the allele of Fy^a. The accompanying table shows the reactions of the red cells of Mrs. Hahn and her family with anti-Fy^a, and, where possible, with her own serum. Owing to shortage of this serum no attempts were made to absorb out the contained anti-A and anti-B, and all tests, both of the family and of other specimens, were confined to blood of group O. The family results are clearly consistent with the hypothesis here put forward.

During the whole course of the investigation fifty-nine specimens of known reactions with anti-Fy^a were tested with the new serum. Of these, twenty-eight were positive with both, eleven with anti-Fy^a only, and twenty with the new serum only; none was negative with both. The probability of obtaining such a result by chance if the sera were unrelated is 1 in 167.

One hundred unselected blood specimens were tested in Berlin with the new serum, of which seventy-nine were found to react, this corresponding well with the theoretical proportion of 83·17 per cent of Fy^b reactors in the English population, based on the calculations of Race and Sanger[2].

While this work was in progress, Drs. R. R. Race and Ruth Sanger had been carrying out titrations of large numbers of blood specimens with an anti-Fy^a serum. They had assigned scores to the titrations in the manner described by Callender and Race[3], and had found that these scores fell clearly into two classes, with very few intermediates, the lower scores corresponding to heterozygotes Fy^aFy^b in all cases where the genotype could be deduced from family studies. They very kindly allowed us to make use of these results.

Twenty specimens showing low Fy^a scores and therefore presumed to be heterozygous were tested with the new antibody and all were found to be positive. Seven showing high scores were all negative with the new antibody. The probability of obtaining such a result by chance with two unrelated sera is about 1 in 900,000. Moreover, three of the twenty presumably heterozygous specimens could be shown, from genetical studies with anti-Fy^a alone, to be actually heterozygous. These tests were confined to bloods which gave clear-cut results in the Fy^a titrations; but we afterwards tested with the new serum two specimens which gave intermediate scores with anti-Fy^a. One was, in fact, found to be positive and one negative with the new serum, the positive one, contrary to expectation, giving the slightly higher score with anti-Fy^a.

Sixteen tests with the new antibody were carried out by a titration technique. Of the eleven specimens giving positive results, two showed markedly higher titres than the rest. These two were the only Fy^a-negatives in the series.

These observations appear to furnish conclusive proof that the new antibody is anti-Fy^b. The possible existence of a rare third allele of Fy^a and Fy^b, giving rise to reactions with neither antibody (or with both), is not, however, ruled out.

A further specimen of serum was obtained from the donor ten weeks after delivery, but was found to contain very little antibody. Further investigations must therefore await the development of a more powerful antibody, either in this or some other human subject, or possibly in an animal.

If good supplies of both antisera, anti-Fy^a and anti-Fy^b, should become available, the gene frequencies are such that the system would be a most useful one for purposes such as personal identification and the exclusion of disputed paternity.

We should like to thank Drs. R. R. Race and Ruth Sanger for allowing us to quote their unpublished observations, and Dr. D. Lehane, who supplied the anti-Fy^a serum used in the investigation.

Complete Sporogonic Development of *Plasmodium berghei* in Experimentally Infected *Anopheles* spp.

SINCE the discovery of *Plasmodium berghei* by Vincke and Lips[1], repeated attempts have been made to infect various anopheline and culicine mosquito species with this plasmodium in the laboratory. Oocysts and sporozoites have been observed in naturally infected *Anopheles dureni*[2], but apart from the finding on two occasions of small numbers of young oocysts in experimentally infected *A. maculipennis* var. *atroparvus*[3], no sporogonic development of *P. berghei* under experimental conditions has hitherto been described.

In this preliminary communication we are able to report successful laboratory infections of *A. stephensi* with *P. berghei*, and the complete sporogonic development of the parasite from young oocysts in the mid-gut to mature sporozoites in the salivary glands.

The strain of *P. berghei* used in the present experiments was a recently isolated strain producing large numbers of mature gametocytes in infected mice and rats. This strain (*S.P.* 28 *S.* Keiberg) was derived from sporozoites of a wild-caught *A. dureni* inoculated into white rats. The strain was received through the courtesy of Prof. J. Rodhain on January 11, 1951, and has been maintained in the laboratory by blood inoculation. Previous attempts to infect *A. stephensi* with this strain met with only slight success. Although exflagellation was found to occur regularly, only small oocysts were observed, occurring singly or in small numbers, in eight *A. stephensi* from a total of 93 dissected.

In the present experiment a group of 120 *A. stephensi* were fed on a rat infected with *P. berghei*. 29 mosquitoes dissected at intervals up to fourteen days later showed no evidence of oocyst or sporozoite development. 76 *A. stephensi* surviving from this group were allowed to feed on a golden hamster (*Mesocricetus auratus*) infected seven days previously by blood inoculation, and 15 were maintained as controls on raisins only. All the mosquitoes were kept at a temperature of 26–27° C. and at high humidity in the insectary. Dissections of stomachs and salivary glands were made from the fifth day onwards.

All stages in oocyst development have been seen in the dissected *A. stephensi*. Mature oocysts containing sporozoites were observed at the end of the seventh day and after. Sporozoites in the salivary glands were found by the twelfth day. The fully developed sporozoites measured 11·5–13 µ in length. The number of sporozoites in the salivary glands was found to be surprisingly small, and the percentage of infected glands was low (3 out of 23, or 19 per cent of mosquitoes dissected from the tenth day after feeding) compared with the oocyst infection-rate. Of 71 *A. stephensi* dissected 52 were found to be infected, giving an infection-rate (oocysts and/or sporozoites) of 73 per cent. None of the controls showed evidence of infection.

The results obtained show that *A. stephensi* under laboratory conditions will produce mature oocysts containing sporozoites in a very high percentage of mosquitoes fed on infected hamsters, and that under the experimental conditions described only a small number of the sporozoites reached the salivary glands. The very high infection-rate produced in *A. stephensi* fed on a hamster infected with *P. berghei* demonstrates the usefulness of *M. auratus*[4] as a mammalian host in the laboratory study of *P. berghei* infections.

This work has been carried out in the Department of Parasitology, London School of Hygiene and Tropical Medicine, in collaboration with the Ross Institute. We wish to thank Prof. H. E. Shortt and Dr. P. C. C. Garnham for their advice and encouragement.

Nov. 9.

A similar technique was used for investigations on *A. maculipennis* and *A. quadrimaculatus*.

Thirty-five laboratory-bred *A. maculipennis* var. *atroparvus* and ten *A. quadrimaculatus* were allowed to feed on hamsters infected with the *S.P.* 28 Keiberg strain of *P. berghei* and showing mature gametocytes in the peripheral blood. The mosquitoes were kept in the insectary at 26–27° C. and at a high humidity. Dissections started from the third day onwards, and revealed moderate and high oocyst infections (see photomicrographs) in both these species. Oocysts on the fourth day averaged 7 µ, on the fifth day 11 µ, on the sixth 16–18 µ, and on the seventh day 18–21 µ. Ripe oocysts were detected from the eighth day onwards and averaged 30–34 µ. The first detection of sporozoites in the salivary glands occurred on the ninth day after feeding. Of 29 *A. maculipennis* dissected, 18 were infected (62 per cent); of 10 *A. quadrimaculatus* dissected, 7 were positive (70 per cent).

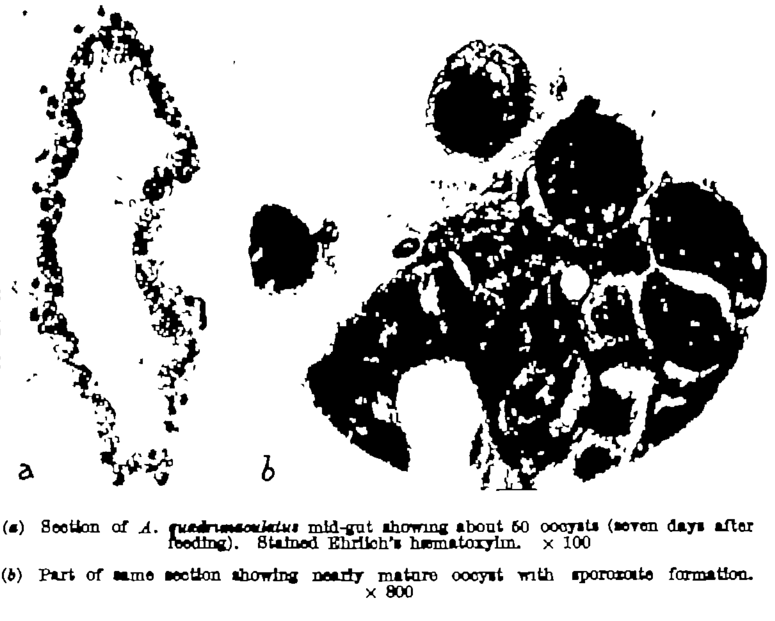
The development of the oocysts under the experimental conditions described was rapid; on the fourth day some oocysts showed advanced nuclear division.

Black spores and chitinization of sporozoites in the ripe oocysts and in the salivary glands occurred in a number of infected mosquitoes from the tenth day onwards.

Successful laboratory infection with *P. berghei* (*S.P.* 28 Keiberg strain) has now been established in three different species of mosquitoes: an Indian oriental species (*A. stephensi*), a European palæarctic species (*A. maculipennis* var. *atroparvus*), and a north American species (*A. quadrimaculatus*).

Transmission of *P. berghei* by inoculation of sporozoites from ruptured oocysts (of *A. stephensi*) into a young hamster has been carried out. Parasites were first found in the blood on the tenth day after inoculation.

This work has been carried out in the Department of Parasitology, London School of Hygiene and Tropical Medicine, in collaboration with the Ross Institute. We have pleasure in acknowledging the



(*a*) Section of *A. quadrimaculatus* mid-gut showing about 60 oocysts (seven days after feeding). Stained Ehrlich's hæmatoxylin. × 100

(*b*) Part of same section showing nearly mature oocyst with sporozoite formation. × 800 assistance given by the technical staff of the Ross Institute.

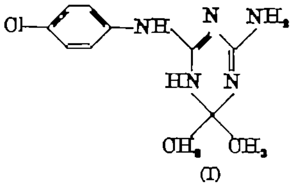
A Metabolite of 'Paludrine' with High Antimalarial Activity

Since the discovery of 'Paludrine' (proguanil, N^1-*p*-chlorophenyl-N^5-*iso*propyldiguanide) by Curd, Davey and Rose[1], considerable evidence has accumulated that this drug probably differs in its mode of action from most other antimalarials. Direct evidence that proguanil is transformed in the animal body into another, more active, compound was provided by Hawking[2] and Hawking and Perry[3], who showed that proguanil has no action on *in vitro* cultures of the exo-erythrocytic forms of *Plasmodium gallinaceum* or on the blood forms of *P. cynomolgi*, whereas, under similar conditions, serum from animals dosed with the drug has high antimalarial activity.

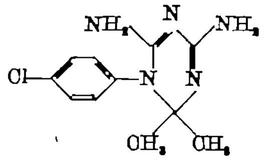
Experiments have therefore been in progress for some years with the object of isolating and identifying this hypothetical metabolite of proguanil, and these have now been successful. From the urine of rabbits receiving daily doses of proguanil (50 mgm./kgm.), there has been obtained a basic substance, isolated first as the picrate, crystallizing from ethanol in canary-yellow needles of melting point 206°, and then as the free base, which crystallized from a mixture of moist chloroform and ether in colourless prisms of melting point 146°. The same product has also been isolated from the fæces of rabbits, and from the urine of human volunteers receiving proguanil. Experiments have shown that the metabolite is about ten times as active as the parent drug against infections of *P. gallinaceum* in chicks.

Analysis of the picrate and of the free base showed the empirical formula of the metabolite to be $C_{11}H_{14}N_5Cl$, the molecule having two atoms of hydrogen fewer than that of proguanil. When the base is heated, either alone or in alkaline aqueous solution, it is readily converted into an inactive isomeric substance which is identical with a compound prepared by Birtwell, Curd, Hendry and Rose[4] from N^1-*p*-chlorophenyldiguanide and acetone in the presence of piperidine, to which the structure 4-amino-2-*p*-chloroanilino-1 : 6-dihydro-6 : 6-dimethyl-1 : 3 : 5-triazine (I) had been assigned. The two isomers are readily distinguished by their chemical and physical properties, and especially by their ultra-violet absorption spectra. The chemical evidence indicates that the active metabolite is 2 : 4-diamino-1-*p*-chlorophenyl-1 : 6-dihydro-6 : 6-dimethyl-1 : 3 : 5-triazine (II), and this structure has been confirmed by an X-ray crystallographic analysis by Miss M. Bailey and Dr. A. F. Wells.

Crounse[5] has described the isolation of two substances as metabolites of proguanil, namely, the inactive triazine (I) and N^1-*p*-chlorophenyldiguanide.



(I)



(II)

In view of the easy conversion of (II) into (I), and its ready hydrolysis to N^1-*p*-chlorophenyldiguanide by dilute acid, it seems likely that neither of these substances was a primary product of metabolism, but that both were derived from (II). We ourselves have no definite evidence of the direct production of either of them from proguanil in the animal body.

The condensation of N^1-*p*-chlorophenyldiguanide with acetone by Birtwell *et al.* had been carried out under conditions in which the active metabolite is not stable, but by modifying these conditions an easy synthesis of the desired substance has been achieved[6]. The synthetic method has been applied to a wide range of diguanides and aldehydes and ketones. The antimalarial activity of the dihydrotriazines thus formed is in the main parallel to that of the corresponding diguanides, but at a much higher level. In particular, 2 : 4-diamino-1-(3 : 4-dichlorophenyl)-1 : 6-dihydro-6 : 6-dimethyl-1 : 3 : 5-triazine shows outstanding activity, with an effective dose of about one-hundredth that of proguanil against *P. gallinaceum* in chicks.

Details of this work will be reported elsewhere.

Occurrence of Thin Membranes in the Surface Layers of Human Skin and in Finger Nails

As reported earlier[1], wool fibres are enveloped by a thin membrane, the epicuticle. This structure is also found not only on human, horse and other animal hairs, but also on feathers[2]. Since structures of this type seem to be rather common, a few more animal structures have been investigated.

Thin pieces of skin loosened from sun-burnt human back were treated with 1 per cent sodium sulphide at 50° C. for six days followed by treatment at room temperature for fourteen days. This treatment is similar to the method used for isolating epicuticle from wool[3]. The residue was washed with water and examined in the electron microscope after shadowing with palladium at an angle of 4 : 1. Pieces of the type shown in Fig. 1 were found. The thickness of the pieces are of the order of magnitude 100 A., which is the same as for the mem-

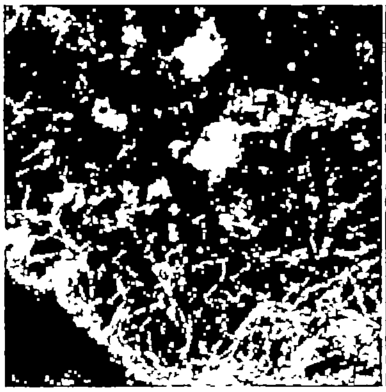

Fig. 1. Folded membrane from skin of the human back. Palladium shadowing, 4 to 1

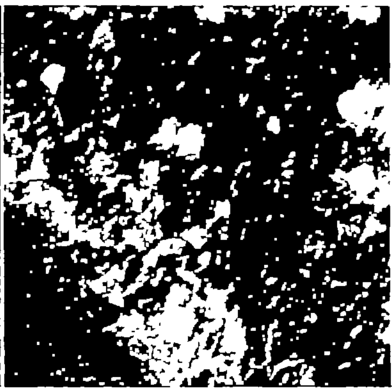

Fig. 2. Membrane from thickened skin from the palm of the hand. Palladium shadowing, 4 to 1

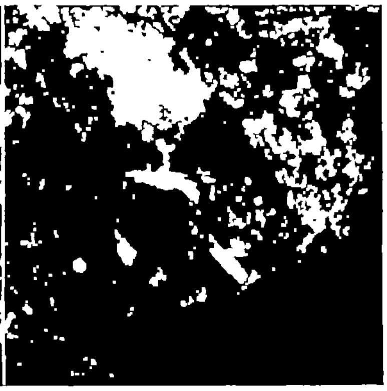

Fig. 3. Membrane from finger nail. Palladium shadowing, 4 to 1

branes earlier mentioned, and the diameter of the pieces is approximately 20–30 μ. In contrast to the membranes from hairs and feathers, the membranes from the skin are wrinkled to a much higher degree. The wrinkles are here running in all directions, whereas the membranes from wool and other hairs are mostly folded in one direction. This difference might be due to different geometrical arrangements. The membranes previously observed envelop cylindrical structures, whereas the membranes originating from the skin might envelop ellipsoidal structures, such as cells.

Thickened skin from the palm of the hand was cut off and treated in the same way. Membranes of the same type were obtained (Fig. 2). Finger-nail parings were also treated in the same way, with similar results (Fig. 3); this structure is also of the epicuticle type, but is more contaminated by extraneous material. This might be expected because of the degree of hardening of this material. Similar structures to those obtained from human skin have been observed in specimens from horse's skin from which the hairs had been removed using Ellis's method[4].

As hyaluronidase has been widely used as a 'spreading factor', it may be of some interest to mention that epicuticle from wool, examined in the electron microscope after treatment with hyaluronidase at 40° C. at different pH's for two days, showed some evidence of being attacked. Damage to the epicuticle of wool will usually give an increased rate of acid sorption by wool fibres[5]. If, however, wool was treated with hyaluronidase at 40° C. at about pH 7 for one day, no increase in the rate of acid sorption could be observed.

We wish to thank Prof. Nils Gralén for stimulating discussions. One of us (G. L.) is indebted to the International Wool Secretariat for a research fellowship enabling him to carry out studies on the epicuticle.

A Resistant Membrane in Wool

IN a recent communication, Mercer[1] disputes our isolation[2] of a resistant membrane situated below the scales and surrounding the cortex of the wool fibre on the basis of experiments with membranes prepared by an entirely different method. He contends that the membrane consists of a thin film originating from the outside of the scales, and called the epicuticle, to which adhere, as contaminants, cuticular remnants.

The following points show this view to be unsound. (*a*) The tubes have considerable strength and can be manipulated to show osmotic phenomena[3]. The epicuticle, approximately 100 A. thick, could not provide the necessary strength, since it can represent at most 2 per cent by weight of the membranes as isolated by our method. (*b*) The same membrane can be obtained from wool the epicuticle of which had been completely removed[4]. (*c*) There is no evidence that the epicuticle forms a coherent film over the whole of the fibre, and detailed work by Müller[5] indicates that it never extends over more than one scale. (*d*) The membrane has a chemical composition distinctly different from that of the fibre as a whole[6]; it represents a definite fraction of the fibre (8–10 per cent), and since the same quantity is always obtained whatever the variation in the extraction technique, it is unlikely to consist almost wholly of adventitious impurities. (*e*) Microscopic observation during the isolation indicates that the membrane is below the scales and surrounds the cortical cells; Zahn and Haselmann[7] have confirmed this unambiguously by sectioning hair with a razor and extracting mechanically a chemically resistant membrane from the surface of the cortex.

The confusion concerning the membrane in wool arises from the fact that in 1944 Lehmann[8] claimed to have isolated a membrane very much thinner than that found by us, which was shown in Prof. Gralén's laboratory to consist of epicuticle and scales only. Gralén *et al.*[9] have made a careful electron microscopic examination of membranes prepared by us and conclude: "The main part of it is probably the outer, resistant part of the cortex . . . nothing indicates that this membrane should be identical with the subcutis of Reumuth, Lehmann, and Elöd and Zahn which originates from the outside of the fibre . . . the membrane isolated by them [Alexander and Earland] is a new discovery not identical with Lehmann's subcutis". Mercer's experimental evidence, which was obtained with membranes isolated by a procedure completely different from ours, is therefore irrelevant and does not invalidate our results. He does not appear to have examined a membrane of the type studied by us.

Bamford *et al.*[10] have already dealt with the next criticism made by Mercer, namely, that the membrane could not be present in the β-configuration in the original fibre since no β-reflexions are visible in its X-ray photo. We pointed out in the original publication[2] that an unoriented β-phase would probably not be detected among crystalline α-keratin by X-rays; a conclusion that has since been confirmed in another system by Bamford *et al.*[11].

Finally, Mercer contends that we ascribed the insolubility of the membrane to the fact that it is in the β-form. We have not made such a claim; on the contrary, we stated quite clearly[2] that the β-configuration was *not* sufficient to account for the insolubility of the membrane and suggested the presence of non-disulphide cross-links. There can be little doubt that the same protein is less soluble when in the β- than when in the α-configuration, and we demonstrated this by converting the soluble α-keratose into the β-form. Ambrose *et al.*[12] found afterwards that silk behaved in a like manner.

Earlier this year, Peacock *et al.*[13] examined membranes prepared by them according to our methods and claimed that these were in the α-configuration and suggested that our membranes had been converted to the β-configuration by heat denaturation. Our preparations, however, were never heated above room temperature, and on repeating our experiments we have again found the membranes to be in the β-form. The soluble α-keratose dissolves slowly because of its high molecular weight, and it seems possible that the preparation of Peacock *et al.*[13] was contaminated with this α-material. This would also explain why their tubes changed from α- to β-configuration on heating, since we have found[14] that the soluble α-keratose readily undergoes this transformation. To ensure that the membrane is free from α-keratose, it must be shown to weigh no more than approximately 10 per cent of the original fibre.

In conclusion, it may be said that no unambiguous proof exists that the membrane is present in the fibre in the β-form and that it is not changed from α to β during isolation. Since in the extraction process the majority of the wool retains the α-configuration, there seems to be no reason why the configuration of the membrane alone should be altered. It seems definite, however, that there is present in wool fibres (and possibly in all keratin fibres) a fraction contributing approximately 10 per cent by weight, which resists dissolution after breakdown of the disulphide bonds, even in such powerful protein solvents as cupriethylene-diamine and concentrated lithium bromide. This material must therefore be considered as a separate component of the wool fibre.

Submicroscopic Structure of Fibres and their Formation

From electron microscope investigations it is known that the cellulose in the walls of all plant cells so far studied consists of discrete submicroscopic fibrils[1-4]. This is also true for the cellulose of bacteria[5] and tunicates[6] (electron microscope studies by B. Rånby on tunicate cellulose are also proceeding at this Institute).

According to some authors[1-3,5], the fine fibrils of plant and bacterial cellulose have diameters which lie between 250 and 400 A. Others have reported a value of the order of magnitude 100 A. for the fibrils of plant cellulose[4,7,8]. A constant diameter of about 200 A. was measured for the fibrils of tunicate cellulose[6]. The length of the cellulose fibrils is indefinite.

It was interesting to find that even dissolved and reprecipitated cellulose, in the case of viscose rayon, is built up from submicroscopic fibrils which are about 100 A. wide[9]. At the time of this observation, it was inappropriate to discuss the problem as to whether or not these fibrils may have their origin in crystalline residues of native cellulose which have been preserved during preparation of the specimens.

In order to approach this question and to gain a more general knowledge of the nature and formation of fibres, the morphological and structural investigations have been extended. To this end, chitin, which possesses a micellar framework like cellulose, has been investigated at the same time as synthetic polyamide fibres and polyethylene plastics. These studies were carried out by means of electron microscopy, electron and X-ray diffraction.

In crustacean tissues of varying physiological functions, fibrils of a thickness of about 100 A. were again found to be a structural element[9]. The different structural patterns of specific types of tissues depend on differences in the organization of these fibrils.

Also in fibres of polyamides (for example, the polymer of ϵ-amino-caproic acid), a system of submicroscopic fibrils was found to form a structural unit[10]. As is known, such a fibre is formed when the fibrous molecules are crystallized from a melt with artificial orientation. Even in a polyethylene plastic bundles of fibrils were observed[10]. The fibrils of these two synthetic products are morphologically identical with those of cellulose and chitin. All samples investigated were dispersed by means of ultrasonic waves before electron microscopy. Wood, chitinous tissues and viscose rayon fibres were studied also in thin, unfragmented microtome sections. Both methods gave pictures showing the same kind of fibrillar units. Thicker products, obtained after ultrasonic treatment, could always be split up further and shown to consist of elementary fibrils. There was nothing to indicate a splitting of the elementary fibril itself.

Hence the submicroscopic fibril is not specific for cellulose, but is obviously a quite general morphological element which may be formed when linear macromolecules order themselves in a lattice (macromolecular lattice, according to Staudinger and Signer[11]). Indeed, it might be expected that molecules which are chemically different but of similar structure, and therefore crystallizing in the same type of lattice, would form colloidal aggregates of the same shape and size.

According to modern views, the formation of a micellar structure[12] is due to the fact that long-chain molecules have an exactly parallel orientation over a given region. The linear macromolecules may then pass through several such ordered regions. If it is supposed that a fibril is built according to modern micellar theory, the areas of lattice order will occur with colloidal dimensions also in the direction of the fibril, and not only perpendicular to it.

As a modification of Frey-Wyssling's[13] theory of the micellar framework structure of cellulose, the idea will be stressed here that the dimensions of the crystallized areas perpendicular to the main valence chains correspond quite generally to the thickness of the submicroscopic fibrils (of the order of magnitude 100 A.), which was observed by means of electron microscopy. This has earlier been suggested for cellulose[7,8] and was clearly confirmed, in a rather unexpected way, by investigations on chitin[9]. The studies on chitin made it possible to exclude objections which might otherwise have been valid.

For the formation of a system of elementary fibrils with the character of a fibre, an external orienting force is necessary.

From the investigations on viscose rayons[8] and polyamide fibres[10], it may be concluded that there is already a pervading system of the fine fibrils before the orientation is high enough to give an ideal fibre diagram. An orientation of a higher degree may then be due to the elementary fibrils orientating themselves parallel to one another. In the case of the viscose rayon, the crystallinity does not increase thereby.

An orientation mechanism is necessary also for the formation of the cellulose fibres of plants. As is known, the fibre character of plant material is due to the structure of the secondary walls of the cells. The fibrils of these walls are formed at the surface of the plasma. In this case, the orienting effects come from the streaming of the plasma. The discrete fibrils appear, therefore, in lamellar layers, the fibrils of which are orientated in a parallel manner in the direction of the plasma stream.

Hence, from the results reported here, it seems that the observed structure of viscose rayon[8] is not necessarily due to crystalline residues from the native cellulose.

I wish to express my thanks to Profs. T. Svedberg, A. Tiselius and S. Claesson for their great interest in this work.

Stimulation by Insulin of *In vitro* Fat Synthesis by Mammary Tissue studied with Carbon-14 and Tritium

RESPIRATORY observations have been interpreted[1] as indicating that lactating mammary gland slices are able to utilize acetate for net fatty-acid synthesis *in vitro*, either as sole substrate (ruminants: sheep, goat, cow) or in the presence of glucose (non-ruminants: rat, rabbit). Tissue respiration measurements have, moreover, led to the further conclusion[2-4] that insulin, added *in vitro*, causes a marked stimulation of fat synthesis by lactating mammary gland slices from rat, rabbit and mouse.

This striking *in vitro* action of insulin has now been investigated by the isotope incorporation technique. In experiments on mammary tissue from lactating rats killed at the 14th–15th days of lactation, approximately 2-gm. batches of slices were incubated for 3 hr. at 37° with 0·02 *M* sodium acetate (containing 10 µC., or in later experiments 1 µC., $CH_3{}^{14}COONa$) and 0·3 per cent glucose, dissolved in 20 ml. Krebs–bicarbonate–saline (containing 200 µC. TOH), in equilibrium with 95 per cent oxygen and 5 per cent carbon dioxide. The total fatty acids were isolated from the tissue and their calcium salts treated by combustion in oxygen. The carbon dioxide and water thus produced were stripped from the gas stream by means of liquid-air cooled traps. The carbon dioxide was separated from the water by sublimation *in vacuo* at – 78° and counted in an internal gas counter; the water was converted to butane for determination of tritium as described by Glascock[5]. Each experiment included a control incubation in which the tissue was killed at the outset by addition of acid, and in all cases the incorporation of carbon-14 and tritium into the fatty acids was very small compared with the value after a 3-hr. incubation.

It will be seen from the results of eight experiments reported in the accompanying table that insulin (1 I.U./ml.) increased the carbon-14 content of the fatty acids 1·4–4·5 times and the tritium content 1·3–5·0 times. The increases in the carbon-14 content of the fatty acids due to insulin were in many cases greater than those reported by Brady and Gurin[6] for liver slices incubated in acetate.

The carbon-14 determinations confirm previous conclusions drawn from respiratory results on the marked ability of lactating mammary tissue to incorporate acetate carbon into fatty acids *in vitro* and the stimulation of this process by insulin.

Exp. No.	^{14}C in fatty acids (c.p.m./mgm. C) × 10^{-3}		T in fatty acids (c.p.m./mgm. combustion water)	
	Insulin		Insulin	
	–	+	–	+

7*	2·8	12·5	46	223
8*	5·5	12·0	117	306

* 1 µC. sodium acetate in 20 ml. medium in these experiments; 10 µC. in all others

The results on the incorporation of tritium into fatty acids more generally illustrate the ability of mammary tissue to synthesize fatty acids from small molecules, and in agreement with the carbon-14 observations further confirm the insulin effect. The results point to the usefulness of tritium as a label for body water, since it can be measured at much lower concentrations than deuterium.

Influence of Adrenotropic Hormone Fractions on 'Adrenal Repair' and on Adrenal Ascorbic Acid

WE have studied[1] the activity of pituitary extracts in the Sayers test[2], which depends on ability to induce a rapid fall in the ascorbic acid content of the adrenal glands of hypophysectomized rats, and in an adrenal 'repair' test based on the increase in the adrenal weight of the rat hypophysectomized one to three weeks previously and given three intraperitoneal injections daily of pituitary extract for three days, the animal being killed on the fourth day. Since an adrenal weight-increasing effect (*AW* effect) does not necessarily measure only changes in the weight of active cortical tissue, such an effect is necessarily less precisely defined than an ascorbic acid reducing effect (*AA* effect). In our investigation of these two activities of different pituitary extracts, we have adopted as our standard for the ratio *AW*/*AA* the pig pituitary preparation 84–85 *U*, kindly supplied by Armour Laboratories, Ltd.; this preparation is about 2·5 times as active in the ascorbic acid reduction test as the Armour standard preparation *La*-1-*A*, the provisional International Standard. We have followed three main lines of investigation, which it will be convenient to consider separately.

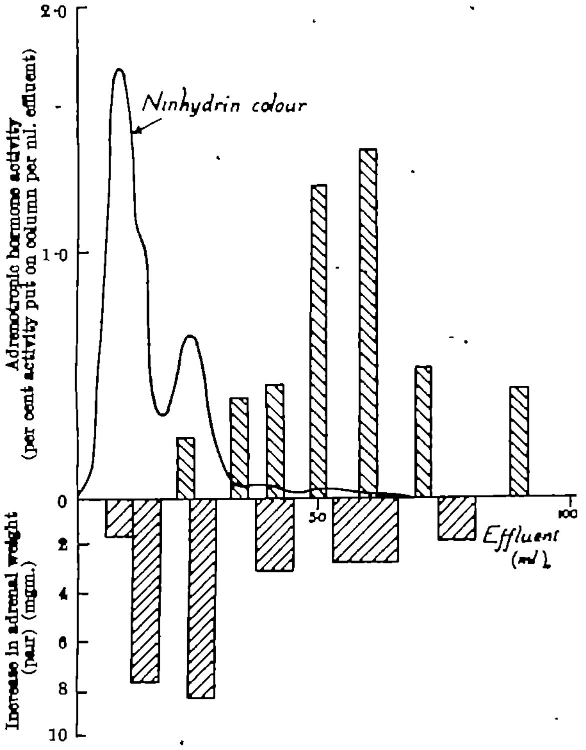
Activity of crude pituitary extract. For crude extracts of sheep, pig or beef pituitary glands, prepared by acid–acetone extraction, *AW*/*AA* does not differ significantly from that of our standard, that is, unity. Nevertheless, crude alkaline extracts of ox anterior pituitary tissue rich in growth hormone but with very slight *AA* activity yield *AW*/*AA* ratios up to 5,000/1. Growth hormone[3] was found also to show significant *AW* activity in a total dose of 20 mgm., though its ascorbic acid reducing activity was so small that 20 mgm. of the hormone was equivalent to only 2·2 μgm. of 84–85 *U* in this respect. The ratio of activities of the growth hormone was about 800/1.

When a total of 20 mgm. of growth hormone was given under the conditions of the adrenal weight increase test, histological examination revealed the presence of lipid in the site of the former sudanophobe zone[4] with many mitotic figures in the cortex. With a preparation highly active for the reduction of ascorbic acid (84–85 *H*) in a dose (0·5 mgm.) considerably greater in *AA* activity but much less in *AW* activity than 20 mgm. of growth hormone, there was also a return of lipid to the sudanophobe zone, but mitotic activity was much less than with growth hormone treatment. A dose of 84–85 *H* (2·5 μgm.), approximately equivalent in *AA* activity to 20 mgm. of growth hormone, produced no repair of the sudanophobe zone or significant change in the weight of the adrenal glands. In view of the large doses of growth hormone needed in these tests, and the probability that the growth hormone preparations used may be contaminated with traces of other hormones, it is not necessary to assume that the growth hormone itself is the active factor.

The crude alkaline extracts of ox pituitary tissue we have used contain only about 0·01 per cent of the total *AA* activity calculated to be present in the original pituitary tissue, while the *AW* activity of these extracts is 2–20 per cent of that extractable by other means, for example, by acid–acetone extraction. The possibility arises that the *AA* activity is almost completely destroyed in the process of extraction (by pituitary enzymes ?) but that the *AW* factor is more stable under these conditions.

Activities of purified ascorbic acid reducing fractions. Two pig pituitary preparations were supplied by Armour Laboratories, Ltd., preparation 84–85 *H* being derived from 84–85 *U* by a process which involves partial hydrolysis by heating in acid solution. If the *AW*/*AA* ratio for 84–85 *U* is taken as unity, the ratio for 84–85 *H* is found to be about 1/8. This suggests that the *AW* activity of 84–85 *U* is more labile towards acid hydrolysis than is the *AA* activity, a fact which is in accordance with some recent results of Reinhardt and of Li[5]. Nevertheless, there may be some substance in 84–85 *U* which has a potentiating effect on *AW* activity and which is more labile towards acid hydrolysis than is the *AA* activity. We consider, however, that this is unlikely. The preparations which are more highly purified with respect to *AA* activity might be more quickly absorbed and excreted and thus be less effective in a long-term test, such as that for increase of weight of adrenals, than in the ascorbic acid reduction test, which lasts only one hour. Accordingly, we have carried out adrenal weight tests with preparations mixed with substances designed to slow absorption from the peritoneal cavity. When a solution of freeze-dried plasma was added just before injection to give a final concentration of 3 per cent, there was little or no potentiation of the activities of 84–85 *H* and 84–85 *U* in such a test. When, however, tannic acid was added just before injection to give maximum precipitation, or alumina paste was added, potentiation of the *AW* activity of both 84–85 *H* and 84–85 *U* was observed, the *AW*/*AA* ratio of both being increased about five-fold. Since the difference between the two preparations remains, it seems unlikely that the original difference in *AW*/*AA* ratio between 84–85 *H* and 84–85 *U* can result only from a difference in the rate of absorption of the two preparations from the tissues of the rat.

Fractionation of unhydrolysed adrenotropic hormone preparations on an ion exchange resin[6]. In the accompanying diagram is given a typical result for the fractionation on 'Amberlite *IRC*-50' (Rohm and Haas Co.) of a crude adrenotropic hormone preparation obtained by the method of Astwood and his collaborators[7] from pig's pituitaries. In order so far as possible to equalize the rates of absorption from the intraperitoneal tissues in the adrenal-weight test, samples for that assay were mixed just before injection with 0·025 per cent (final concentration) of serum albumin or casein and then tannic acid sufficient to give a maximum precipitation (0·0125 per cent). All the fractions active in the ascorbic acid reduction test also possessed *AW* activity (see diagram), but the faster-running fractions produced very large adrenal glands indeed in the *AW* test, although they showed only slight *AA* activity. These results strongly



Chromatogram of 'crude corticotropin' (ref. 7) on 'Amberlite *IRC*–50' (200–400 mesh) in 0·2 *M* sodium phosphate buffer pH 6·60 containing 0·2 per cent phenol and 0·5 per cent thiodiglycol. 475 mgm. of crude corticotropin was extracted with 9·5 ml. of the buffer and 8 ml. of the solution put on a 2 cm. × 29 cm. column. Weight of untreated adrenals, 9·0 mgm.

suggest that *AW* and *AA* activities can be separated by a process which does not involve hydrolysis.

We do not know if all the effects described above can legitimately be attributed to the presence of only two factors in the pituitary gland. It seems necessary, however, to assume the existence of at least two factors which may be described under the term adrenotropic hormone.

We are grateful to the Nuffield Foundation for generous support of this work and to Armour Laboratories, Ltd., for the gift of adrenotropic hormone preparations 84–85 *H* and 84–85 *U*. One of us (H. B. F. D.) wishes to express his thanks to the Medical Research Council of Ireland for a studentship held while much of this research was carried out.

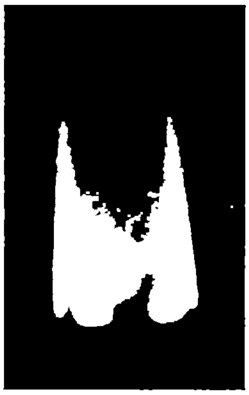
Polyhedral Diffusion Flames

BURNER flames of unusual structure may be obtained when certain hydrocarbon gases and vapours are burnt in admixture with air or oxygen. Thus, as first noted by Smithells and Ingle[1], and later by Smith and Pickering[2], the inner cones of the flames may assume the form of a polyhedron, the number of sides of which is dependent upon prevailing conditions, and which may or may not rotate about a central, vertical axis. More recently, Mann[3] and Behrens[4] have reported the occurrence of polyhedral flames using weak mixtures of hydrogen and air.

During the course of an investigation into the processes responsible for the formation of polyhedral flames, we have observed that the phenomenon is not confined solely to aerated flames, but may occur also with flames of the diffusion type provided that an inert gas be mixed with the inflammable gas prior to combustion.



The accompanying photograph is of a diffusion flame produced when a mixture of hydrogen and carbon dioxide, containing 19·35 per cent of the former, is burnt at atmospheric pressure upon a cylindrical tube of 1·1 cm. internal diameter. The flame, which will be seen to be composed of five bright segments separated by dark lines, could be made to rotate or to remain stationary by adjusting the rate of flow of the mixed gas.

Similar polyhedral diffusion flames have been obtained when nitrogen instead of carbon dioxide was used as the diluent gas.

An account of our investigation is to be published shortly.

The Lotmar–Picken X-Ray Diagram of Dried Muscle

THE publication by Lotmar and Picken[1] of an X-ray photograph of a certain dried muscle preparation produced considerable interest and controversy, since, in addition to indicating an unusual degree of crystallinity, the diagram showed no sign of the 5·15 A. meridional arc which hitherto had been regarded almost as a diagnostic feature of the X-ray photographs of α-fibrous proteins. While we do not wish to enter the controversy as to whether or not Lotmar and Picken's photograph is indeed that of myosin, or any other protein, we should in passing like to point out the striking resemblance between their photograph and that of an oriented film of poly-γ-methyl-L-glutamate, published by Bamford, Hanby and Happey[2]. Recently, Pauling and Corey[3] have claimed that Lotmar and Picken's results support their suggestion that the polypeptide chains in fibrous proteins have their α-helical configuration, particularly in that the fibre axis translation of 5·65 A. calculated by Lotmar and Picken is in good agreement with the distance in the axial direction between adjacent turns of the α-helix. It is therefore perhaps worth while pointing out that the fibre repeat deduced by Lotmar and Picken is not consistent with certain features of their fibre diagram, and that the true value (or a submultiple) should be about 5·3 A.

Lotmar and Picken remark that the absence of diatropic reflexions makes the estimation of the fibre repeat somewhat uncertain. However, consideration of the semi-angle χ subtended at the centre of the diagram by the strong reflexions on the first layer line shows immediately that the repeat r cannot be as large as 5·65 A. Thus, for the reflexions (I_1) corresponding to d = 4·80 A., χ = 22° 40′; whereas the calculated value assuming r = 5·65 A. is 30° 34′. This discrepancy is well outside the probable error of measurement and indicates that r is actually less than 5·65 A. The same conclusion follows from the positions of the other reflexions on the first layer line. It may readily be shown that the value χ = 22° 40′ corresponds to a fibre repeat of about 5·26 A. The χ-values for the other reflexions on the layer line also correspond to this repeat.

This value is consistent with the main d-distances listed by Lotmar and Picken, and also with those given earlier by Herzog and Jancke[4], as shown in the accompanying table. The calculated values are those for a monoclinic cell with a = 12·0 A., b = 5·3 A. (fibre axis), c = 9·8 A., β = 76°. While the agreement between calculated and observed values is only fair, it is probably as good as Lotmar and Picken's, and within the limits of accuracy of the measurements. This unit cell is therefore preferable to that of the earlier authors, since it is consistent with the observed χ-values. The calculated density, assuming two residues per unit cell, has the satisfactory value 1·26 gm./c.c.

OBSERVED AND CALCULATED d-VALUES

	Herzog and Jancke	Lotmar and Picken	Calculated
Equator	10·00	9·24	9·50 (001)
	6·40	6·56	6·62 (10$\bar{1}$)
	5·79	5·94	5·85 (200)
		4·71	4·75 (002)
	3·92	3·96	4·08 (10$\bar{2}$)
		3·73	3·94 (201) 3·90 (300)
		3·49	3·45 (202)
		2·94	2·92 (400)
		2·74	2·62 (10$\bar{3}$)
Meridian	5·23		5·30 (010)
1st layer line	4·89	4·80	4·80 (110)
	4·66		4·64 (011)
		4·26	4·14 (11$\bar{1}$)
		3·96	3·92 (210)
		3·62	3·64 (012)
	3·44		3·30 (212)
	3·10		3·17 (310)
		2·72	2·72 (013)
		2·51	2·56 (410)

If these results can be applied to the fibrous proteins, it is clear that, in order to be satisfactory in this respect, the α-helix will require compression to reduce its pitch from about 5·65 A. to rather less than 5·3 A. This might introduce difficulties, for example, by producing improbably short hydrogen bonds. Further, the axial translation per amino-acid residue would thereby be reduced to 1·43 A., which is appreciably smaller than the spacing (1·50 A.) observed by MacArthur[5] and by Perutz[6], and considered by the latter to refer to this axial translation.

Note added in proof. Since this communication was written, Bear and Cannan[7] have published an X-ray diagram of dried muscle generally similar to that of Lotmar and Picken, but which shows distinct diatropic reflexions. These authors calculate a fibre repeat of 5·3 A., in excellent agreement with our value obtained from the original Lotmar and Picken diagram.

Blue Sun and Moon

Paul and Jones[1], discussing the blue sun caused by selective absorption of a cloud of uniform spheres of radius r in light of wave-length λ, have considered the curve relating K (the ratio of effective to geometrical cross-section of a particle) and α, where $\alpha = 2\pi r/\lambda$. They suggest a simple physical explanation of the maxima and minima of this curve on the basis of resonances. The maxima and minima in the case of small dielectric spheres can also be explained from the principles of physical optics; this point of view was used by Van de Hulst[2] in considering some aspects of the subject that could not so readily be treated by electromagnetic theory.

Interference occurs between the portions of a wave-front passing through a particle and through the adjacent continuous medium. The opacity of a particle has maximum and minimum values when these two are in opposite and like phase respectively. That is, approximately, when n is an odd or even integer in the relationship $2r(\mu - 1) = n\lambda/2$, where μ is the refractive index of the particle relative to the surrounding medium, when

$$\alpha = \frac{2\pi r}{\lambda} = \frac{n\pi}{2} \Big/ (\mu - 1). \qquad (1)$$

Furthermore, if the cross-section of an incident beam is S and the much smaller cross-section of a particle in the beam is s, and if the incident amplitude is B per unit area, then for maximum opacity, that is, opposite phases, the intensity transmitted in the forward direction is $[B(S - s) - Bs]^2$, and the relative transmission is $t = B^2(S-2s)^2/B^2S^2 \approx (1-4s/S)$; the 4 in this expression is the value for K, which agrees with that given for the first maximum in Fig. 1 of Paul and Jones's communication.

Obviously, the different paths through the sphere give different retardations, and more exact calculations[3] have been made by dividing the wave-front through the sphere into annular zones and calculating the phase and amplitude in the forward direction, using Kirchhoff's diffraction formula, for each zone. Some of the results are shown in the accompanying table. The value of K calculated for the first maximum is 3·66 compared with 3·8 from electromagnetic theory[4,5]. Considering that elementary diffraction theory is not expected to be very exact for particles only $3\lambda/2$ in diameter, the agreement is fairly satisfactory.

Values of $2\pi r/\lambda$ corresponding to Successive Maximum and Minimum Values of K, for Water Drops

	Max.	Min.	Max.	Min	Max.
Calculated from equation 1	4·7	9 4	14 1	18·8	23 5
Calculated by Lothian and Chappel[3]	5·0	10·0	14·7	20	25
Calculated from electromagnetic theory[4]	6·2	11 6	16	21	

The name for the coefficient K is not yet generally agreed. Different authors[1–5] have used the terms 'extinction', 'scattering area coefficient' and 'total scattering coefficient'. It is suggested that the first term should be avoided because it is generally used—in Great Britain at least—to denote the quantity $\log_{10}(1/t)$. I myself prefer the term 'total scattering coefficient'.

Calculation of χ^2 for a 2 × 2 Table

SEVERAL algebraically equivalent methods are in use for calculating χ^2 for a 2 × 2 contingency table; but there is one attractive algorithm that does not seem to have been described. Write the table and its marginal totals in the usual notation:

a	b	$a + b$
c	d	$c + d$
$a + c$	$b + d$	N

where $N = a + b + c + d$. Let A be the difference between the two observed ratios when the table is read across, so that

$$A = a/(a + b) - c/(c + d).$$

Similarly, let D be the difference when the table is read downwards, so that

$$D = a/(a + c) - b/(b + d).$$

Then it can be shown that

$$\chi^2 = ADN.$$

The computer may write in the four ratios instead of, or in addition to, the marginal totals. This method is easily memorized, leads to a simple computation, and has the advantage of bringing prominently to notice the actual ratios being compared. To apply the Yates correction, add or subtract 0·5 in the usual way before calculating A and D.

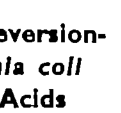
Enhancement of the Normal Reversion-rate of a Serineless *Escherichia coli* Mutant by Certain Organic Acids

SOME mutant genes involving loss of function are known to be capable of reversion at the specific locus; this fact implies that in mutant organisms particular genes are not necessarily destroyed, but may be merely altered, or 'inactivated' with respect to the specific reaction they once controlled. The gene is, so to speak, in an inactive allelic state—but one which can revert or back-mutate to the active allelic state of the wild-type parent. Can environmental conditions other than general mutagenic agents enhance the reactivation of a mutated gene to its original allelic state? It is conceivable that the presence of certain common metabolites, the configuration of which is related to the damaged enzyme – gene system, might, by some as yet unknown mechanism, have such an influence. In various connexions, 'substrate-induced mutations' have been previously discussed[1–3].

It has been found that the normal back-mutation rate of a mutant of *E. coli* (*P.A.*1.5), requiring either serine or glycine, is strikingly enhanced in the presence of certain organic acids not serving as substitutes for serine, but sharing the configuration



$$\left(\begin{array}{c}\text{COOH}\\ |\\ \text{CHOH}\\ |\end{array}\right)$$

namely, 3-phosphoglyceric, glyceric, lactic, tartaric and malic acids. Malate is apparently the least active. Natural D(+) tartaric acid is active; the L(−) form is inactive. The reversions in the presence of these acids give rise to cell types both partially and fully independent of serine or glycine. In control experiments with other acids (or none) the great majority of reversions are to full independence, or wild type; intermediate types are rare.

The fluctuation test of Luria and Delbruck[4] for determining mutation-rates was used. Forty 2·5–3·0 ml. cultures were shaken at 37° C. in 20-ml. Freudenreich flasks for 39 hr. Control cultures, as well as cultures containing glycerate, lactate, etc., contained a glycerol-minimal medium, pH 6·2, supplemented with an amount of glycine in slight excess of that necessary for maximum growth of the (inoculated) dependent mutant. This mutant grows in such a medium with about the same generation time (1·5–2·0 hr. at 27° C.) as does the reverted, fully or partially independent cell type. Plating 1-ml. samples from the individual cultures (20 experimental and 20 control) to minimal agar revealed the numbers of independent cells which had arisen and multiplied during incubation.

The results of a typical experiment are given in the accompanying table; essentially the same results are obtained if (1) each culture is centrifuged, the cells washed, and plated to purified agar; (2) the same amount of tartrate which is transferred to the plates from the primary experimental cultures is also added to the control plates. Therefore, selective survival of mutants on the plates due to the transfer of tartrate, glycerate, or some unknown substance does not occur. Microscopic examination at various times of regions with no reversions on the control and experimental plates reveals no differences with respect to cell density or distribution. Reverted types are referred to as fast, intermediate, or slow synthesizers, depending upon their ability to

REVERSIONS IN THE PRESENCE OF GLYCERIC AND SUCCINIC ACIDS

* The plates were selectively numbered after reverted colonies began to appear.

† *Corrected for sampling.*

'F' indicates a fast synthesizer (wild type), 'I' an intermediate, 'S' a slow, and 'VS' a very slow synthesizer. The plates were observed and colonies counted after 48, 56 and 72 hr. of incubation at 35° C. Generally speaking, fast synthesizers were observed after 48 hr., and intermediate or slow after 56 or 72 hr.

synthesize serine and glycine, and hence upon their rate of growth on the minimal agar plates. The glycerate concentration was $0 \cdot 2\,M$, and the succinate $0 \cdot 1\,M$.

The mean number of back mutants per culture is 101; the variance is about 42,000.

After incubation of the liquid cultures, the pH of the glycerate series had dropped to 5·6, and the succinate series to pH 6·1; other experiments demonstrate that pH differences between the two series of this order of magnitude do not affect the results. Both types of cultures had reached $1 \cdot 5 \times 10^{9}$ cells/ml. Summarizing the results of this and three similar experiments reveals that, in the controls, 14 out of 80 cultures contained one to six independent bacteria; in the glycerate series, 55 out of 80 cultures contained 1 to 10^{4} (full and partial) reverted cells. The concentrations of glycerate were between 0·15 and $0 \cdot 2\,M$; the enhancement of reversions is greater with increasing amounts of this acid. Despite the extremely high concentrations, it seems unlikely that a general mutagen present as an impurity is the effective agent, since (1) the calcium glycerate, barium phosphoglycerate, and tartaric acid used were in a highly purified crystalline form; (2) the sources of the effective acids are very different: glycerate and lactate were synthesized chemically, phosphoglycerate and tartaric were isolated from natural sources; (3) the D-, but not the L-, form of tartaric acid is active. Such high concentrations may be necessary at the pH used in order to have enough undissociated acid present. Studies of the dependence of rate of reversion on the pH of the cultures are in progress. Related acids in control cultures were used in the highest non-toxic concentration possible; those found to be without influence on the rate of reversion are: citrate, succinate, adipate, acetate, formate, oxalate and malonate.

It is conceivable that as many phenotypically expressed mutants arose in the control as in the experimental series, but that their multiplication was for some reason selectively inhibited in the former cultures. To test this possibility, it is best to plate out all of each control culture to see how many flasks contain any mutants. Such experiments were done, plating both to minimal agar and to minimal agar supplemented with tartaric acid. The number of cultures with mutants was no greater than would be expected on the basis of results obtained from sampling some two hundred control cultures. Sampling cultures in the presence of the highest possible concentrations of DL-glycerate and D(+)-tartrate ($0 \cdot 2\,M$ and $0 \cdot 03\,M$ respectively) showed that at least 57 out of 60 cultures contained reversions, as contrasted with 14 out of 30 completely plated-out cultures in the control series. The difference is highly significant ($P < 0 \cdot 01$ by the χ^2 test).

There are two alternatives to the conclusion that the phenomenon described is a specific, environmentally induced mutation.

(*a*) It is possible that glyceric acid, lactic acid, etc., are non-specific mutagens, under the conditions of testing described above. Using a sensitive technique[5] for testing the mutagenic effect of substances on a micro-conidiating strain of *Neurospora crassa*, it was found[6] that glyceric acid is not a strong or moderately strong general mutagenic agent. Glyceric and tartaric acids were also tested for their influence on the rate of reversion of a tryptophaneless and a histidineless *E. coli* mutant, and found to be without effect. Nevertheless, however extensive, such experiments cannot make it possible to claim that these acids could never induce mutations in a less specific way.

(*b*) It is conceivable that, by some unknown mechanism, the effective acids allow the phenotypic expression of the mutations, which actually occur as frequently in the absence as in the presence of these acids[7]. Such a situation would have many aspects (for example, specificity) in common with a directed mutation; it would be difficult, if not impossible, to distinguish experimentally between the two alternatives.

In the presence of glycerate, the relative numbers of fast, intermediate and slow back mutants on individual plates suggest that the faster types arise from the slower ones. The 'intermediate' or partially reverted cell types which so frequently arise in the presence of the effective acids retain their characteristic generation times (as originally seen during their initial growth in liquid minimal medium) for many weeks and often months when cultured on complete media[6]. Their peculiar characteristics will be described in a later publication, to appear in *Comptes Rendus des Travaux du Laboratoire Carlsberg*, Série Physiologique.

This work was supported by a predoctoral fellowship of the National Institutes of Health while at the Hopkins Marine Station, Stanford University, California, and by a postdoctoral fellowship of the National Research Council while at the University of Copenhagen and Carlsberg Laboratorium, Copenhagen.

Formation of New Cell Walls in Cell Division

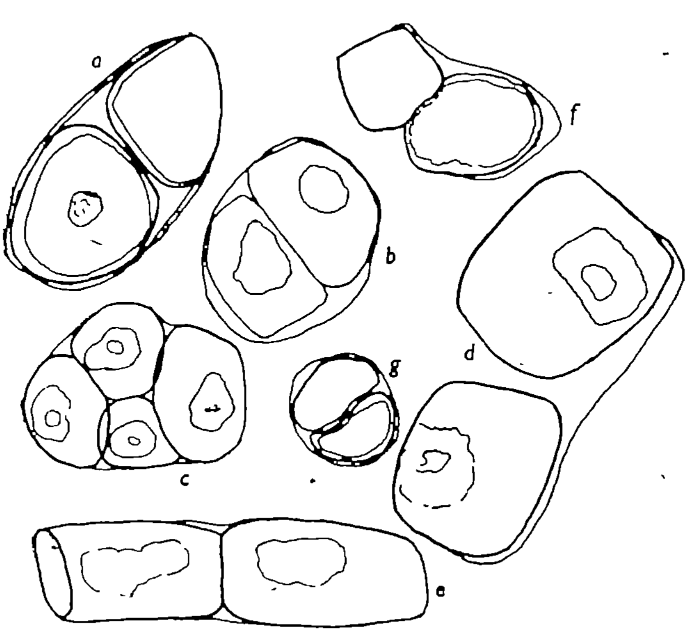
In 1882 Giltay[1] suggested that the new cell wall was not a partition separating the daughter protoplasts, but that the latter each secreted a continuous wall around itself; the two daughter cells remaining for a time within the stretched wall of the parent cell.

This suggestion was neglected until 1938, when Priestley and Scott[2] published evidence of the phenomenon in the parenchyma, collenchyma and sclerenchyma of dicotyledons. This evidence was based on a maceration technique which dissolved the middle lamella, leaving only cellulose walls. Observations on such macerated material showed files of daughter cells surrounded by the stretched wall of the original parent cell.

I have applied this maceration technique to a number of flowering plants and found the phenomenon common to both stem and root tissues. This treatment has produced the same results in the rhizomes of *Aspidium* and *Equisetum*, the stem of *Sphagnum*, the thallus of *Lunularia* and the cortical cells of *Fucus* (see Figs. *a*–*g*). Another example of this type of cell-wall formation in the algæ is reported for *Dictyosphaeria favulosa* by K. Wilson[3].

Priestley and Scott hesitated to attribute this mode of wall formation to meristematic cells of the shoot apex, in view of the lack of information on the nature of these cell walls and their behaviour under maceration. It is, however, interesting to note that in the transverse section of the shoot apex of *Lupinus albus*, Ball[4] depicts groups of cells surrounded by a common wall.

More data are required before generalizations may be made, but the above evidence derived from representatives of the Bryophyta, Pteridophyta and Spermatophyta suggests that this mode of cell wall formation may be universal in the higher plants.



Camera lucida drawings (⅙″ objective; reduced to ½) of macerated material of (*a*) *Lupinus albus* stem, (*b*) and (*c*) rhizome of *Aspidium*, (*d*) rhizome of *Equisetum*, (*e*) stem of *Sphagnum*, (*f*) thallus of *Lunularia*, (*g*) cortical cells of *Fucus*, showing groups of cells enclosed or partially enclosed in the original parent cell wall. In most cases the cells are showing plasmolysis

The 'Golgi Substance'

In *Nature* of August 11[1], Dr. A. J. Dalton described the appearance under the electron-microscope of the 'Golgi substance' in cells of the mammalian intestinal epithelium and liver. During a period of many years I have devoted a great deal of attention to the part of the intestinal epithelial cell studied by Dr. Dalton and have reported my results in full[2].

To find out what lies in this part of the cell, it is necessary to make one's examination before the cell has undergone any visible changes resulting from its death. The intestinal epithelial cell of the mouse can easily be examined in what is usually called a 'supra-vital' state; that is, the living tissue can be removed from the body and at once examined in a suitable saline solution. The cells undergo no visible change for a considerable time. Under phase-contrast the so-called Golgi region (close to the nucleus and on the side of it directed towards the free border) can be seen to contain a number of separate spherical or sub-spherical bodies, some of them containing one or more vacuoles. These bodies I call lipochondria. I reject the name 'Golgi apparatus', because that, by Golgi's definition, is a network.

Lipochondria are easily stained supra-vitally with neutral red or dahlia. If one wishes to have a permanent preparation, one should use the sudan black method[3], though even this may somewhat distort them. The non-vacuolate bodies are lipoid all through; the vacuoles, when they occur, do not contain lipoid.

I have demonstrated these lipochondria of the living cell to others repeatedly (for example, in my classes in the University, at the meeting of the Association of British Zoologists in London in January 1950, and to Prof. Jean Brachet during his visit to Oxford in the same month), and am prepared to do so again.

The classical 'Golgi apparatus' consists of particles of osmium hydroxide or of silver deposited in or on various objects in various cells: in this particular cell on the lipochondria. Silver has a strong tendency to produce an artificial appearance. It is as though one were to try to find the shape of a group of transparent spheres by throwing particles of mud at them and recording accurately the shape assumed by the mud. Naturally enough, it often assumes the shape of a net. One could alter the appearance at will by throwing more or less mud, and the same applies in making silver preparations of the cell.

Osmium has less tendency to produce an artificial effect, and if it is used sparingly it can give a life-like appearance to lipochondria[3]. If the latter are crowded together and too much osmium is used, it artificially joins them. Dr. Dalton's Fig. 2*B* shows them quite well; but the osmium has been deposited in such a way as to join nearly all the lipochondria into groups.

When an object is sufficiently large to be seen with the light-microscope, there is no purpose in trying to determine its form by use of the electron-microscope. On the contrary, it is necessarily more distorted than it would have been if it had passed through the ordinary routine of microtomy, because it must be perfectly dry. The electron-microscope has value only in throwing light on sub-microscopic structure.

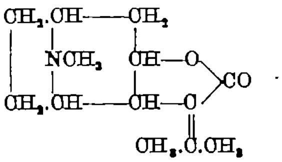
An Alkaloid of *Dioscorea hispida*, Dennst

THE alkaloid dioscorine, $C_{13}H_{19}O_2N$, was first isolated in 1894 by Boorsma[1] from *Dioscorea hirsuta*, Bl., and obtained in a crystalline condition by Schutte[2]. On the basis of degradation experiments, Gorter[3] in 1911 suggested that the alkaloid belonged to the tropane group, and proposed the following structure:



In 1937, Leyva and Gutierrez[4] isolated from the tubers of *Dioscorea hispida*, Dennst, a base which gave the same colour reactions and possessed the same toxicological properties towards mice and monkeys as dioscorine. Although the base could not be crystallized, and no derivatives were described, these authors considered their product to be identical with dioscorine.

In this Laboratory, the isolation of the alkaloidal material from *D. hispida* has been repeated by a modified procedure. From 3·5 kgm. of the tubers, 2·0 gm. of an oily base was obtained. The base, which was purified through its hydrochloride, distilled *in vacuo* without decomposition, and gave the same colour reactions as dioscorine. It crystallized on keeping, and formed beautifully crystalline derivatives, all of which gave analytical figures in support of the formula $C_{13}H_{19}O_2N$ for the alkaloid. The accompanying table shows how the properties of the alkaloid and its derivatives compare with the properties of dioscorine as described in the literature.

It seems that, in spite of discrepancies, the base may be identical with dioscorine; but this question must be regarded as *sub judice*. An investigation of the molecular structure of the substance is in progress. The ultra-violet and infra-red absorption spectra show that an αβ-unsaturated lactone system is present. On oxidation with acid permanganate the base yields only formaldehyde, and the absence of acetaldehyde and acetone as products of this reaction would appear to exclude an ethylidene and an *iso*propylidene group respectively. It may be concluded that either Gorter's formula for dioscorine must be revised, or that the base from *D. hispida* is not dioscorine.

	Dioscorine (m.p.)	Alkaloid from *D. hispida* (m.p., uncorrected)
Free base	43·5° (ref. 2)	54–55°
Hydrochloride	204° (ref. 2)	210–211° (decomp.)
Methiodide	213° (ref. 3)	203° (decomp.)
Picrate	183–184° (ref. 2)	187° (decomp.)

I am grateful to Sir Robert Robinson for his interest in this investigation.

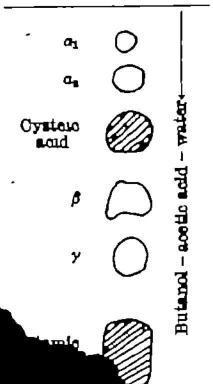
Artefacts in the Chromatography of Mixtures of Amino-acids containing Cysteine

IN the course of an investigation of the amino-acid metabolism of *Staphylococcus aureus*[1], using paper partition chromatography, I used the bromine water oxidation method, devised by Consden and Gordon[2], to avoid trouble during the separation of mixtures containing cysteine. The following procedure was used: to a neutralized solution of cysteine and glutamic acid (10 mgm. per ml. of each acid) enough bromine water is added to oxidize all the cysteine to cysteic acid (about 0·1 ml. of bromine water saturated at 20° C. per mgm. of cysteine hydrochloride); the solution is then evaporated to dryness *in vacuo* at room temperature to remove the slight excess of bromine and the hydrobromic acid formed during the reaction. The residue is dissolved in a small amount of distilled water and dried three times, then made up to the original volume and neutralized. Chromatographic separation on paper (Whatman No. 1 or No. 3), with butanol/acetic acid/water as solvent[3], shows, as illustrated on the diagram, four unexpected spots giving slowly a reddish-purple colour with ninhydrin. The two top ones (α_1, very weak, and α_2, stronger) give, after elution and acid hydrolysis (in 6*N* hydrochloric acid, 3 hr. at 105° C.), strong cysteic acid spots on a new chromatogram. The two others (β, strong, and γ, weak) run between the two initial amino-acids and are hydrolysed into cysteic and glutamic acids; they move also as single spots in a propanol/water mixture[4] (80 : 20, v : v). These spots are not due to incomplete oxidation, since excess of bromine water does not prevent their appearance; working at 0° C. does not affect the result.

New spots are also obtained when other amino-acids (glycine, alanine, valine, serine, arginine) and also triethylamine are used instead of glutamic acid; they move in butanol/acetic acid/water between



cysteic acid and the other compound. If thiomalic acid is present instead of cysteine as —SH group carrier, new materials are also formed. They give but a weak brownish colour with ninhydrin, as might have been expected, and glutamic acid is liberated on hydrolysis.

Hydrogen peroxide, replacing bromine as oxidizing agent, produces identical but weaker spots; autoxidation of the solution gives only trails due to incomplete reaction.

Nothing is known about the chemical link between the of these must be the sulphur spots do not appear after the absence of sulphydryl acid solution, but α_1 and α_2 en cysteine alone is oxidized. ip might be the amino group, ven as yet; the facts support- re the slowness of the appear- spots and their weakness when ose of the amino-acids obtained of an equivalent amount of product; sts the unmasking of amino groups. On hand, deamination of the compound giving (see diagram) according to Consden, d Martin[5] leads to the complete dis- of both amino-acids after hydrolysis; be due to the liberation of the presumedly ed amino groups in the strong acid solution hydrochloric acid) in which the reaction takes place.

f Deoxyribonucleosides on Paper Chromatograms

chromatography of deoxyribonucleo- described by several workers[1–4]. The e located on the chromatogram by r ultra-violet light[1,6,7], by a micro- [3,5] or by means of the Feulgen [4]. A colour reaction between and cysteine in sulphuric acid Dische[8,9]. This has now been etection of deoxyribonucleosides on atograms. While all the deoxyribosides, s deoxyribose itself, give the reaction, neither nor the ribonucleosides can be detected by hod.

The reagent consists of a solution of cysteine hydrochloride (0·5 gm.) in 3 *N* sulphuric acid (100 c.c.). The air-dried chromatogram is sprayed with the solution. After 5–10 min. at 85°, pink spots appear. Quantities of 10–20 μgm. can be easily detected when the compounds are introduced to the chromatogram in 1 per cent solution. Spots containing more than about 50 μgm. of the compound are pink with a brown centre. The purine deoxyribosides react more rapidly than the pyrimidine derivatives, especially at 75°, due to their labile glycosidic linkage. There is, however, no difficulty in detecting the pyrimidine compounds. This is a distinct advantage over the earlier chemical tests, in which colour development with pyrimidine deoxyribosides is slow (in the Feulgen and Dische reactions), or which lead to gross decomposition of the filter paper (Dische reaction)[4]. A certain amount of care is necessary in handling chromatograms after treatment at 85°. The colours fade rapidly on exposure to light, and if a permanent record is required it is advisable to photograph the chromatogram immediately after development of the colour.

The R_F values of the naturally occurring deoxyribonucleosides in two solvent systems are given below. The butanol solvent gives fairly good resolutions of the pyrimidine deoxyribosides, while the alkaline phosphate system resolves the purine derivatives.

Compound	*n*-Butanol saturated with water	5 per cent Na_2HPO_4 in *iso*-amyl alcohol (ref. 10)
Cytosine deoxyriboside	0·23	0·77
5-Methylcytosine deoxyriboside (ref. 11)	0·25	0·76
Thymine deoxyriboside	0·51	0·78
Uracil deoxyriboside	0·38	0·79
Adenine deoxyriboside	0·35	0·55
Guanine deoxyriboside	0·21	0·62
Hypoxanthine deoxyriboside	0·23	0·70
2-Deoxyribose	0·36	0·87
2-Deoxygalactose	0·23	0·86

It is hoped that this technique, together with the phosphate spray of Hanes and Isherwood[12] and the other procedures mentioned above, will facilitate the rapid analysis of compounds obtained by the degradation of nucleic acids and in synthetic work in this field.

My thanks are due to Drs. D. M. Brown, C. A. Dekker, D. T. Elmore and W. S. MacNutt for the gift of samples: to Prof. A. R. Todd for his encouragement, and to Glaxo Laboratories, Ltd., for a grant during the tenure of which this work was carried out.

FORTHCOMING EVENT

Thursday, December 27

BRITISH PSYCHOLOGICAL SOCIETY, EDUCATION SECTION (in collaboration with the CONFERENCE OF EDUCATIONAL ASSOCIATIONS, in the Great Hall, King's College, Strand, London, W.C.2), at 2.30 p.m.—Dr. G. Brock Chisholm: "Social Responsibility, or Toward Maturity".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PHYSICAL CHEMIST (experience in instrumental analytical work and with isotopically labelled substances is desirable) as a Senior Research Officer in the Laboratory of Human Nutrition—The Director, University Laboratory of Human Nutrition, Churchill Hospital, Oxford (December 31).

READER IN THE DEPARTMENT OF GEOGRAPHY in the Research School of Pacific Studies—The Administrative Officer in the United Kingdom, Australian National University, 27 Russell Square, London, W.C.1 (December 31).

SENIOR LECTURER or LECTURER IN BACTERIOLOGY, a SENIOR LECTURER or LECTURER IN RADIOLOGY, and an ASSISTANT LECTURER IN PHYSICS, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (December 31).

SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree in physics, preferably with some years research experience) at the Road Research Laboratory, Harmondsworth, Middx., for work on the physical properties of bituminous road binders and surfacing materials—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting A.313/51A (December 31).

ASSISTANT LECTURER (graduate in physics, chemistry or metallurgy) IN DENTAL MATERIALS—The Registrar, The University, Manchester 13 (January 1).

CHIEF TECHNICAL OFFICER (with a University degree in agriculture, and wide experience of hill and upland farming and of the Highland area in particular) for the Hill Lands (North of Scotland) Commission—The Ministry of Labour and National Service. Technical and Scientific Register (K), Almack House, 26–28 King Street, London, S.W.1, quoting G.402/51A (January 1).

LECTURER IN PHARMACOLOGY in the Medical School, Dundee—The Secretary, The University, St. Andrews (January 1).

BIOCHEMIST (with research experience) to work on problems connected with tissue metabolism and the metabolism of cancer producing substances—The House Governor, Royal Cancer Hospital, Fulham Road, London, S.W.3 (January 9).

PRINCIPAL SCIENTIFIC OFFICER (with a first- or second-class honours degree in engineering, or corporate membership of the I.C.E., I.M.E. or I.E.E.) in the Royal Naval Scientific Service at the Underwater Countermeasures and Weapons Establishment, Havant—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4108/52 (January 10).

LECTURER IN MINERAL DRESSING AND ASSAYING in the Department of Chemical Engineering, University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 12).

RESEARCH OFFICER (with a University honours degree in science, with chemistry or biochemistry as major subject, or equivalent qualifications) IN THE DIVISION OF FOOD PRESERVATION AND TRANSPORT at the State Abattoirs, Homebush Bay, N.S.W., to investigate the chemical constitution of plant and animal lipoids, and study changes in lipoids during storage—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 3663 (January 12).

SCIENTISTS II or III, for research in the telecommunications and light electrical engineering fields (Ref. TT/400), and ELECTRONIC ENGINEERS (Scientific Technologist, Grade I, or Senior Scientific Technologist), to design and construct electronic devices for research (Ref. TT/401), at the Central Research Establishment, Stoke Orchard, Cheltenham—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting the appropriate Ref. No. (January 12).

LEVERHULME RESEARCH STUDENTSHIP for research into some aspect of the history or archaeology of London—The Secretary, London Museum, Kensington Palace, London, W.8 (January 15).

MATHEMATICIAN to assist in the preparation of problems for an electronic computing machine (the EDSAC)—The Director, University Mathematical Laboratory, Free School Lane, Cambridge (January 15).

NUFFIELD RESEARCH CHAIR OF MECHANICAL ENGINEERING at the New South Wales University of Technology—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (January 19).

PROFESSOR OF GEOLOGY, and a PROFESSOR OF ZOOLOGY—The Registrar, The University, Reading (January 21).

CHAIR OF CHEMISTRY at the Royal Cancer Hospital—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 22).

ASSISTANT EXAMINERS OF PAPER AND OFFICE REQUISITES (with such *training* in chemistry and physics as will enable them to investigate faults in paper of all kinds and stationers' sundries, and to carry out tests appropriate to the examination of supplies for the public service), H.M. Stationery Office—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 206/52 (January 31).

COW AND GATE FELLOWSHIP for research into problems associated with nutrition in infants and children—The Registrars, The University, Manchester 13 (January 31).

PHYSICS GRADUATE, to assist in isotope tracer research (radioactive elements and mass-spectrometer)—The Professor of Physics, The University, Reading (January 31).

CHAIR OF ANATOMY—The Secretary, Queen's University, Belfast (February 20).

ASSISTANT LECTURER, Grade B (with an honours degree in physics) IN THE DEPARTMENT OF PHYSICS—The Principal, Sir John Cass College, Jewry Street, London, E.C.3.

ASSISTANT METEOROLOGISTS in Nigeria—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27118/5/51.

GRADUATE IN PHYSICS OR PHYSICAL CHEMISTRY in the Division of Biophysics and Optics—The Director, National Institute for Medical Research, Mill Hill, London, N.W.7.

MATHEMATICIAN or MATHEMATICAL PHYSICIST (with a good honours degree and, preferably, some knowledge of the theory of elasticity) for research in applied mechanics—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

PHYSICIST or MECHANICAL ENGINEER (honours degree in physics or mechanical engineering essential, good knowledge of applied mechanics and/or mechanical properties of metals necessary) to lead a team engaged on research into the mechanics of wire and bar drawing, and the mechanical properties of drawn wires and bars—T Personnel Officer, British Iron and Steel Research Association, 11 Lane, London, W.1, quoting 'Wire Drawing'.

PHYSICISTS and ELECTRICAL ENGINEERS (Scientific at an R.A.F. Signals Experimental Establishment in Ministry of Labour and National Service, Technic Register (K), Almack House, 26–28 King Street quoting A.380/51A.

PRINCIPAL METALLURGIST IN THE BRANCH, Windscale Works, Sellafield, work of laboratories engaged on resear active materials—The Ministry of Sup (Production), Risley, Warrington, Lan

PRINCIPAL METALLURGISTS (with a degree in physics, physical chemistry qualification; responsible post-gradua fundamental investigations is essential) tories, Culcheth, Warrington. (a) to be work of laboratories engaged on studies geneous equilibria, using methods of ph graphy, X-ray crystallography and ele supporting studies for research work on p chemistry, surface chemistry and deformatio responsible for research into pyro-metallurgical p responsible for research into powder metallurgy— Supply, Division of Atomic Energy (Production), Risley, Lancs, stating post applied for and quoting Ref. 273.

SCIENTIFIC ASSISTANT for greenhouse experiments, of the experimental work with sand cultures in com vestigations on the mineral nutrition of crops, at the R Long Ashton—The Secretary, The University, Bristol.

SENIOR EXPERIMENTAL OFFICERS and EXPERIMENTAL THE RESEARCH AND DEVELOPMENT BRANCH to unde mental work on a wide range of problems in organic an chemistry, chemical engineering, experimental physics, m heat transfer, welding of non-ferrous and ferrous materials, biology, at laboratories at Culcheth, Sellafield and Salwick— Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, stating post applied for and quoting Ref. 276.

SENIOR LECTURER IN MATHEMATICS—The Principal, Royal Technical College, Salford 5.

SENIOR SCIENTIFIC OFFICERS (with a first- or second-class honours degree in chemistry, physics or metallurgy, or equivalent qualification) IN THE RESEARCH AND DEVELOPMENT BRANCH to undertake research work on a wide range of problems in organic and inorganic chemistry, physical chemistry, thermo-chemistry, surface chemistry, physics, physical metallurgy, mechanical properties of metals and the melting and casting of metals, at laboratories at Culcheth, Sellafield and Salwick—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting Ref. 270.

LEADERSHIP IN THE WELFARE STATE

SEVEN years ago, in "The Price of Social Security", Mrs. Gertrude Williams directed attention to new functions of the trade unions in the social service State under conditions of full employment, as well as to the new demands made on the Civil Service. The late Prof. H. J. Laski, in his book "Reflections on the Revolution of our Time", had already examined some of the implications of social security for the work of trade unions and professional associations, and stressed the part such bodies could play in improving productivity as well as standards of professional practice, of education and of welfare generally.

In conditions of full employment and social security, the protective or negative functions of professional bodies must decline in importance and these positive functions become more significant. The trade unions in Great Britain have, however, shown few signs that they have grasped the significance of this change or the scope of the opportunities for constructive work in fostering technical development and industrial re-organization, and in building and strengthening the new social order opening before them. That the welfare of the members of the trade unions depends in increasing measure on the welfare of the country as a whole has not always been remembered. When Political and Economic Planning published its studies of British trade unionism in 1948, it was recognized that the basic character and aims of the trade union movement were still unaltered: the protection and advancement of the interests of its members were its primary, and sometimes its exclusive, concern, in spite of the experience of co-operation with government and the profound change in the relation of the movement to the rest of society. The studies afforded little evidence that the trade unions were adapting their outlook and practice to the fulfilment of their new role.

This negative outlook persisted in the lectures which Prof. Laski himself delivered in the United States in March–April 1949, just a year before his death. Published last year under the title "Trade Unions in the New Society", these lectures show little trace of the conception of positive functions which Laski had outlined eight years earlier.

To one set of current problems Prof. Laski did direct attention. These are the problems which arise out of the relations of trade unions with nationalized industry. Here he was concerned more especially with the participation of the unions in the management of a nationalized industry. The criteria he suggests are of particular interest in the light of the wider and fuller examination, made recently by the Acton Society Trust, of the practical difficulties which the unions experience once an industry is nationalized and which appear to limit their ability to co-operate in the successful running of the industry, and the implications of nationalization policy for their future role.

Published under the title "The Future of the Unions"*, this is a most disturbing study deserving the attention of all professional bodies having relations with such industries, as well as of those who are concerned with the future and efficiency of productive industry. Even the inter-union problems discussed have their interest for the scientific worker. Such problems have not merely led to disputes over demarcation questions as a result of the efforts of certain nationalized industries to integrate and rationalize their services, or over recognition matters in relation to the 'closed shop': the changed circumstances of former employers and senior executives under nationalization have led to the emergence of what have been termed 'management unions'. Many such men have felt the need for an organization which would represent their interests to the highest level of management and negotiate wage or other agreements. Sometimes professional associations have transformed themselves into negotiating bodies; sometimes new associations have been established for the purpose. But the development which has resulted in the unions representing three main bodies of employees—manual; clerical, technical and administrative; and managerial—has increased the possibility of disputes.

This is notably true in the field of negotiations and joint consultation, nor are the possibilities of friction diminished by the traditional suspicions of the manual workers' unions of clerical and supervisory unions, and now of the new managerial unions. There is little indication that those associations of professional and technical workers which have become affiliated to the Trades Union Congress have been able either to abate such suspicions or instil a more positive and enlightened attitude to present problems.

The modern trade union official must now have sufficient knowledge of the industry to deal with the very wide range of problems which arise in consultation, and he must be able to discuss those questions with management experts instead of merely tabling demands. Defects in union leadership can, in fact, have just as serious repercussions on industrial efficiency as defects in management; but nothing like enough attention has yet been given to this question either inside or outside the unions. It was just indicated by Mr. S. G. Raybould in his recent book "The English Universities and Adult Education"; but the implications for trade unionism of the new educational policy and particularly of the freer access to universities were not considered. No policy of education for leadership, however, can avoid having regard to this issue: it would be fatal to industrial harmony and efficiency if none of the first-rate minds of each generation found their way into the trade union movement or received the intellectual training which enabled them to develop their gifts and use them to the fullest advantage in the service of the unions.

The reason for viewing the situation disclosed by this inquiry with such concern is that little or no attempt has been made by the unions to prepare in advance to meet the difficulties just discussed, and to dispel the lack of realism in the thinking of their members about nationalization and participation in management without having regard to the wider responsibilities involved. The warnings of Laski and others appear virtually to have been ignored, and there is little evidence on the basis of this inquiry that the unions have even begun consideration of the very considerable programme of training and education required.

This, to put it bluntly, is dereliction of leadership, and such dereliction will not fail to bring its own retribution. If the unions, in nationalized industry or elsewhere, continue to ignore the positive aspect of their functions, they may well find themselves unable to exert their traditional protective functions effectively.

The only way in which a union can secure a real increase in wage values for its members is by an increase in efficiency or productivity, or both. The only alternative is an intensifying inflation in which the value of wages increasingly falls behind the advance in prices. Under present conditions, even more than when Laski made the point in his Sidney Hillman lectures, a union in asking for better conditions must establish that there is increased output per man-hour or an obvious increase in the worker's responsibilities in a particular trade, and must put the full emphasis on the first. Only the prompt recognition of these responsibilities and opportunities will enable the unions to safeguard the standards already attained, still more to move from an era of security into one of abundance.

This is essentially a task for the trade unions themselves, and though some union leaders have already shown a clear grasp of what is at stake, the inquiry carried out by the Acton Society Trust provides little evidence that the task is being attempted on a wide basis and will be accomplished in time. The association of the Trades Union Congress with the industrial training courses commenced at Ashridge this year is a much more hopeful sign. Grounds for optimism are also to be found in activities of the Workers' Educational Association, and thi
Association may well come to play a decisiv
the general educational work which mus
recognition and analysis of these proble
unions.

There are other bodies too, like the A
Trust, which can assist in the process by formu
clearly the principles which should govern the relatio
between management and workers in a nationaliz
industry, and the series of studies being made by t
Trust are clarifying some of the issues and indicat
some of the principles which should find acceptan
Studies already made have endorsed the soundne
of some of the principles which Laski suggested should govern the management of a nationalized industry, notably in regard to decentralization, to methods of promotion and dismissal, and the provision of adequate organs of consultation for explaining at
level decisions which affect workers, so as to co
them that their views have been seriously
before the decisions are given effect.

---

* Nationalised Industry Series, 8: The Future of the Unions. Pp. iii+32. (Claygate: Acton Society Trust, 1951.) 2s.

The more management can do to make such principles fully operative in industry, to associate workers with the formulation and operation of post-entry schemes of training, with welfare schemes and the like, the easier should be the task of the union officials in educating their members and readjusting ideas and policies. There may be some doubts as to how far it is possible, as was advocated by Laski, to elicit the direct co-operation and understanding of the workers in research, and his last point as to political qualifications for executive office in a nationalized industry is liable to be misconstrued and might well be abused in practice. Neither point should be rejected out of hand and without mature consideration, for both could affect strongly that climate of opinion within and without an industry and so powerfully affect its efficiency. The Acton Society Trust itself in a recent study showed how far we are yet from solving the problem of the right use of scientific and technical experts.

There is thus a whole range of problems to which, from outside the trade union movement, the man of science, the technologist and the administrator can contribute much to help the trade unions to find their solution. Even if the unions are late in recognizing these problems, there is a large measure of goodwill on which they can count. Some scientific workers and professional men are, moreover, members of trade unions and may be able to play a part from within; though this study of the Acton Society Trust leaves it at least a little doubtful whether their influence is likely to be either so effective or so beneficial as when exerted from outside. At least it is clear that professional associations need to clear their minds as to their functions and relations with the nationalized industries, and with other bodies where any attempt may be made to apply the policy of the 'closed shop'. Whatever the general attitude of the scientific worker to membership of a trade union, he should be vigilant to see that his own particular professional associations are awake to all the implications of the new situation, and prepared to make their full contribution to the service of society to-day.

BRAINS AND MACHINES

Doubt and Certainty in Science

A Biologist's Reflections on the Brain. By Prof. J. Z. Young. (The B.B.C. Reith Lectures, 1950.) Pp. viii+168+8 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1951.) 7s. 6d. net.

THE eight B.B.C. Reith lectures, which Prof. J. Z. Young broadcasted in 1950, have now been published in book form; they deal with the working of the brain, with processes of learning and communication, and with the development of human society. Their title belies both their scope and character. They are not concerned with any abstract discussion of scientific method, nor does Prof. Young try to illuminate empiricist philosophy with lessons drawn from the laboratory. The brain, he points out, [illegible] continually searching for fresh information about [illegible]ythm and regularity of what goes on around
us". It is this characteristic of human act
which he refers as doubting. Once significa
resemblances are found, a "system of law" e
When this happens certainty results.

The first lecture sets the stage. Prof. Young
briefly explained how the man of science work
the point that man owes his pre-eminence to
that he has developed the power of commu
to a far greater extent than have other anima
cerebral background of this special characte
Prof. Young's particular theme, and his expo
planned so as to avoid the pitfalls of dualism
use of animistic models. In place of the latter
analogies in the world of man-made machines.

The second, third and fourth lectures deal
conduction of the nerve impulse and the
brain functions. Prof. Young introduces the
of cybernetics, and shows how Dr. Wiener's
tion of regulation by 'feed-back' applies t
bodily processes—the analogy being valid i
as feed-back mechanisms maintain the body
steady state and tend to produce actions that
any deviation from this state". Thus "info
provided by each of the receptors tends to
an action by the body that is appropriate to k
life system stable in the light of the change t
receptor reports". Prof. Young takes the
a step further by suggesting that information
vey to other people in our societies is also "an
designed to have some regulating effect".

The second big analogy which he expound
likeness of the brain to a giant modern calc
machine. Such machines 'store' memory, an
with lightning speed. When their kind of mec
is combined with devices that permit of seek
avoiding reactions, it is possible to design '
missiles that can decide between correct and in
responses. This, it may be supposed, is the
brain also operates when it compares one thi
another. Prof. Young pursues this analo
points out that "the major problem is to und
the pattern of activities in the brain by wh
input is fitted with the memory, and produ
action". In his account of the learning pro
leans heavily on Hebb. He describes how peop
blind, who are given their sight by means of
intervention, have "to learn to see the worl
do", because "they have no models with w
compare the input, no mould or filter that
used to select the significant features of visual
ence and produce appropriate words and other
responses". Further, he accepts Hebb's usefu
that repeated stimulation by any pattern of ex
sets up a closed system of excitation between
cells that have become associated during a pr
learning, and that as a result a physical t
ultimately left in the brain.

The final four lectures are more general a
cursive. The fifth speculates about the or
language and of society. The sixth deals w
development of scientific thought, and Prof.
observes that physics can now be regarded as
with the relations between "a man world
servers" and "the reports of what they observe"
sequently, he suggests "a new phase is at h
which a common science of physics and biolo
be necessary". The seventh lecture consid
development of ideas in the biological field.
concluding talk, Prof. Young discusses the
of the concept of evolution on that of individ
elaborating the thesis of the 'continuous' ch

of experience, in which the individual is merely a point in a stream of biological time.

It says much for Prof. Young that an effort is needed to remember that his lectures were designed not for an audience of specialists but for a million or more radio-listeners. If it were not for the danger of this confusion, the only task of a reviewer would be to praise an enthusiastic and highly individual piece of popularization, which imparts new design and colour to a subject that has long been a favourite for general writing. It is difficult not to regret, however, that Prof. Young has had to compress so many of his ideas—a shortcoming which he has tried to remedy by adding five short chapters of comments—and also that popularization has sometimes demanded of him excessive simplification and emphasis.

The major pitfall of simplification derives clearly from the stress of analogies. Modern medicine and biological science forged ahead, as Prof. Young reminds us, when, following the example of Descartes and Harvey, increasing use was made of physical models, and when bodily processes began to be analysed and interpreted in terms of mechanism. The value here, following the lines of Prof. Young's thesis, is that the comparison of "something unknown with something already known makes it possible to talk about the unknown". But the danger is that analogies have the habit of either becoming, as Prof. Young warns, a trap for the unwary to believe that they understand fully when they do not, or, what he could have added, mere figures of speech. Prof. Young argues that man's special characteristic is his capacity for communication, and he develops this thesis in relation to the central feature of cybernetic thought, self-regulation, and to Hebb's views of the changes that take place in the brain as learning proceeds. These two ideas become loosely articulated into one major notion—the brain as a giant calculating machine containing fifteen thousand million cells as opposed to the twenty-three thousand valves possessed by the biggest calculating machine so far built. The analogy obviously helps to drive home a possible way of looking at some cerebral functions. And if the analogy between the working of *A* the brain and *B* the machine were complete, in the sense of an exact correspondence, it would, of course, follow that the brain and the machine were no different from each other. But the analogy is not complete, and its emphasis unfortunately obscures three essential differences: first, that the maintenance of a steady state of behaviour is scarcely compatible with an ever-active learning process and an ever-expanding horizon of experience; second, that the sphere of action of the calculating machine is completely predictable, whereas only by an act of faith could we suppose that the same is true of our brains; and third, that the mechanical brain clears itself of all its memory between tasks or runs, whereas the run of a living brain, and its memory, to all intents and purposes last a lifetime. These differences are every bit as vital as any similarities that can be found between artificial and real brains. It begs the question to imply that the reason why the analogy between them is not more complete is, on one hand, ignorance, and, on the other, the immensely greater complexity of the brain relative to the machine. That is where analogies run the danger of becoming mere figures of speech. If, as the reader is told, we do not know much yet about what goes on in our brains, it can only be figurative to suggest at the same time that "it is possible to use our knowledge of brain functioning to understand even the highest activities of man".

Reference to cybernetic and corresponding models does not illuminate the important facts that the process of learning is itself something that is learnt; that every perceiving individual is an active agent who transforms his percepts—and not just a passive receiver of stimuli emanating from a fixed external world; and that the living brain is self-organizing. It is interesting to note that these ideas, to which Prof. Young directs attention, had also been expressed by William James seventy years ago or more—and probably by many others before him—without the help of analogies drawn from modern communication engineering. "Practical utility," wrote James[1], "wholly determines which parts of our sensations we shall be aware of, and which parts we shall ignore. We notice or discriminate an ingredient of sense only so far as we depend upon it to modify our actions. We *comprehend* a thing when we synthesize it by identity with another thing . . . as soon as we have learned how to behave towards it, and how to meet behaviour which we expect from it." Further, in another essay, James spoke of the indomitable desire "to cast the world into a more rational shape in our minds than the shape into which it is thrown there by the crude order of our experience"—and notes that the world has shown itself "plastic to this demand of ours for rationality". Even if his words do sometimes imply the kind of dualism which Prof. Young avoids, William James would probably have therefore held that cybernetics, like "the latest breeze from the physiological horizon" which he scorned, added little to what was known before about processes of thought. The paradox to-day is that cybernetics makes one feel that some new and completely revolutionary idea about the working of the brain is going to spring at us from some hidden corner, whereas the fact is that cybernetic models scarcely help us to understand how the 'output' of the cortex is controlled or how the 'input' fibres are related to the cortical cells, two essential questions which, Prof. Young reminds us, still remain open. Cybernetic ideas will contribute to the solution of these problems only if, like these Reith Lectures, the interest they excite attracts to the experimental study of the brain research workers who, as Prof. Young tells us, are badly wanted at the present time, and whose recruitment would be more than merited by the importance of the subject.

S. ZUCKERMAN

MORE NEW SYSTEMATICS

Grundlagen und Methoden einer Erneuerung der Systematik der höheren Pflanzen

Die Forderung dynamischer Systematik im Bereiche der Blütenpflanzen. Von Dr. Franz Buxbaum. Pp. xi+224. (Wien: Springer-Verlag, 1951.) 44*s*. 6*d*.

THERE are many signs of a renewal of interest in botanical (and zoological) taxonomy. The practical importance of reliable and easily workable systems of classification is acknowledged by all who need to know with what organisms they are working and wish so to express the results of their experiments or observations that they can be tested and used. The methods of systematic botany are being gre
improved: nomenclature is (one hopes)

stabilized, descriptions on the whole are more adequate, types are more carefully chosen and more definitely designated, more and better preserved material is available than formerly, and new data from ecology, genetics and cytology are being incorporated. The development of the ecological and cytogenetical branches of botany is now influencing taxonomic theory, and taxonomists are being forced to consider the basic principles of biological classification. It is not yet possible to foretell what changes, in practice and in theory, will result from the synthesis of old and new; but, with the natural, and defensible, conservatism of taxonomists, they are more likely to come gradually than to take the form of an abrupt revolution. The introduction of new methods and outlooks is being accompanied by an overhaul of those long established. On the whole, taxonomists have every reason to be proud of their products, in spite of criticism from outside their ranks—criticism which is often more connected with the ignorance of the critics than with errors of taxonomists. Well-informed criticism, however, is to be welcomed.

In the present work by Dr. F. Buxbaum there is much that commends itself to both the practical and the philosophical systematist. Unfortunately, the author has apparently had no opportunity to consult more than a very few of the large number of books and papers published in Britain and the United States during the past dozen years or so on the subjects with which he deals. Thus, there is no reference to Huxley's "The New Systematics" or to the various symposia of which accounts have been printed in the *Proceedings of the Linnean Society* and elsewhere. Probably as a result of relative isolation from contemporary arguments on plant taxonomy, the work can scarcely be considered as a full summary of the up-to-date position in the systematics of the higher plants. Nevertheless, the conclusions of a sincere and thoughtful worker must be of considerable value even if one cannot accept all of them. One must agree that the need for better definitions and for making precise and stabilized terminology is felt by many taxonomists. A modern Lindley or Asa Gray would find much to revise. Even so, it may be noted in passing that Dr. Buxbaum on page 43 uses 'rudiment' when from the context he obviously means 'vestige'. Rightly, he says that in place of naming varieties, etc., a clear comprehension of the range of variation of all varying characters should be the aim.

Dr. Buxbaum's concept of plant taxonomy is that it should be 'dynamic', and by this he means that it should be based on 'progressions' or changes in the genom; but in practice, he says, those changes with a morphological expression must be used. Only direct progressions lead to a step-by-step evolutionary advance, while those without direction give especially variability within a species or genus, most often only in the lower categories. A great deal is made of the concept of 'types'. One must regret that this last word is used with such different meanings in biology; and here is intended not the concrete types by which botanical nomenclature is made precise, but the "Summe aller, der betreffenden Kategorie innewohnenden Formgesetze und Entwicklungstendenzen". A 'type' is not an actually existing phenomenon nor is it identical with a progression, but as a rule is the sum total of unequal but more or less equally directed progressions which determine the course of developnt.

s sounds very nice and is valuable in so far as ects attention to the fact that the phylogenetic relationships of existing taxa can only be traced backwards in the past. The practical difficulties remain: How can 'progressions' be traced with reasonable certainty in the almost complete absence of relevant fossil evidence in the angiosperms? Cytogenetical researches are throwing some light on probable directions of evolution in a few groups, mostly at or about the species level, but little is said about these in the present work. It is, of course, easy—sometimes far too easy—to arrange series of specimens, whether of organs or of organisms, and to postulate that they represent evolutionary or dynamic progressions. Possibly they may, sometimes; but, as other series can be arranged with the same materials, to call any such phylogenetic is an act of faith. This is not to say either that such series-making has no uses or that phylogenetic speculation is in itself to be condemned. What is needed is more phylogenetic research based on fossils and cytogenetics.

Dr. Buxbaum accepts (p. 71) the usual idea that the lower taxonomic cat[illegible]ies in the course of development give rise to the higher. He does not discuss Guppy's reverse view or the possibility of both having some measure of truth. His definition of a 'genus' is worth quoting as it is typical of his point of view: 'Die Gattung ist die Gesamtheit aller Arten, die durch die Einheit ihres morphologischen Typus (Gattungstypus) als stammesgeschichtliche Einheit erkannt wurden" (p. 101). He says that the species concept is a fiction—"die Species keine natürliche Realität ist, d.h. keine unveränderliche und scharf begrenzte Grosse darstellt". Surely, since a genus consists of species, the same conclusion must be reached for this taxon and for other 'higher' taxa also. Dr. Buxbaum has much of value to say regarding the difficulties of applying any concepts of taxa in attempting to make order out of what would otherwise be a chaotic mass of isolated data. He contends that the most important basis of the new phylogenetics is the morphological "Typusforschung": "Der morphologische Typus und seine Entwicklungstendenzen ist das leitende Prinzip der höheren Systematik".

It is obvious that Dr. Buxbaum has been much influenced by the works of Troll on plant morphology. It would be very useful to have a summary of these published in English—particularly of some of the most recent.

That systematic botany is being rejuvenated is evident in many new activities; but its future 'progression' or 'progressions' cannot yet be definitely or fully perceived. In its orthodox form it has well fulfilled a wide range of purposes, theoretical and practical. Possibly for giving latitude and longitude in degrees over the realm of the plant kingdom it will always be of use; but to find position precisely in minutes and seconds a new scheme may be necessary. Taxonomists must certainly take evolutionary concepts more into account. It is becoming increasingly clear, from taxonomic research itself, that, for certain purposes at any rate, we have to abandon the conception of taxa as rigidly definable classes arranged as a hierarchy of species, genera, families, etc., created and maintained as such, whether by the methods of "Paradise Lost", by Linnæus and more recent taxonomists, or by mutation and natural selection. 'Progressions' and 'tendencies' may be vague and difficult to visualize and describe; variations, 'reticulations', and correlations can be dealt with by modern statistical and, to a certain extent, experimental methods. We have as yet no better general scheme of biological classification to replace that which is now in general use and which is dignified by its long record of service. To seek something better is a sign of future progress; to discard what we have until it be found and tested would be foolish. In so far as Dr. Buxbaum's criticisms of orthodox taxonomic theory and practice and his suggestions for improvements help in the search, they will be widely welcomed by taxonomists.

W. B. Turrill

APPLICATIONS AND PRODUCTION OF QUARTZ CRYSTALS

Quartz Vibrators and their Applications

By Dr. P. Vigoureux and C. F. Booth. (Published for the Department of Scientific and Industrial Research.) Pp. xii+371+64 plates. (London: H.M. Stationery Office, 1950.) 30*s*.

THIS book on "Quartz Vibrators" is based on the 1939 edition of "Quartz Oscillators" by P. Vigoureux, but has been made much more comprehensive by revisions and additions of new material on the methods of selecting quartz and producing quartz resonators. Stimulated by the enormous demands for quartz units for frequency stability and for selective purposes which arose during the Second World War, the production of quartz crystals became an important industry. The present book can be considered as a very complete exposition of British practice.

The first few chapters discuss the physical properties of quartz, the occurrence and examination of quartz crystals and give a short exposition of piezoelectric phenomena in crystals. These equations are next applied in deriving the properties of the longitudinal resonator and the thickness resonator. The equivalent electrical circuit for the crystal is used in discussing the stability of a Pierce-type crystal oscillator. The various types of low-coefficient crystals used in oscillators and filters are discussed. The simplest modes of motion and methods for mounting such crystals are described. An excellent chapter discusses the ageing phenomena in quartz crystals and describes methods for getting rid of gross defects. A fine-scale frequency-ageing phenomenon still remains, and it is this effect which produces an ultimate limitation to the accuracy of quartz crystal clocks. The degree of success in producing stable oscillators is discussed, and a day-to-day stability of 1 part in 10^8 is demonstrated. This is ample except for the most exacting primary standards. The use of crystals is described in producing the very selective filters used in the long-distance carrier and coaxial cable systems. A short chapter discusses the use of quartz crystals in under-water sound equipment and in ultrasonics. The remainder of the book is devoted to a very complete discussion of the various methods of sawing, orienting, lapping, etching, plating and mounting quartz crystals.

Several differences between British and American practices may be noted. A number of methods for determining orientation, such as etch pits and cleavage planes as well as X-rays, have been used in British practice, whereas only X-rays have been used in American practice. This latter method has recently been improved by the use of the double-crystal spectrometer, which improves the accuracy with which an angle can be determined. In the field of under-water sound, synthetic crystals such as ammonium dihydrogen phosphate are largely used in American practice in place of the more expensive and less-available quartz crystals.

The book is a very well-written account of the uses of, and manufacturing processes for, quartz crystals. The theories of filters, oscillators and resonators are well presented. The printing is excellent, and many photographs illustrate the manufacturing processes. The book deserves to be purchased by every user and manufacturer of quartz crystals.

W. P. Mason

ANÆSTHETICS

The Mode of Action of Anaesthetics

By T. A. B. Harris. Pp. xii+768. (Edinburgh: E. and S. Livingstone, Ltd., 1951.) 42*s*. net.

THIS book gives a most illuminating account of the mode of action of anæsthetics in man. Dr. T. A. B. Harris has gone to great efforts to give a very accurate and up-to-date account of the way different anæsthetic drugs react when administered to a human being, and has written a brilliant synopsis of the observations which have been made by pharmacologists, physiologists, physicists and biochemists of the mode of action of anæsthetics during the past thirty years.

To undertake a task such as Dr. Harris has done in his book is formidable; yet he has succeeded in giving a clear, concise and intelligent account of the action of anæsthetics in man, while at the same time providing an interesting and stimulating synopsis.

Because of the importance stressed by Dr. Harris of a sound knowledge of the action of anæsthetics, and the body's response to them, his book will be a most valuable contribution to the science and practice of anæsthesia. Only by assimilating all that is known about the pharmacology of a drug can it be given wisely and with maximum safety to the patient, and give favourable operative conditions for the surgeon.

Briefly, the text is divided into four parts. The first deals with the action of narcotics, while in the second a full description is given of inhalation and non-volatile anæsthetics. Part 3 is devoted to the correlation of the level of anæsthetic depression of the nervous system with anæsthetic sleep, loss of sensation and loss of muscle movement and muscle tone, with a special reference to the use of *d*-tubocurarine chloride in clinical anæsthesia. The last section discusses metabolism during anæsthesia and the dominant action and side actions of anæsthetics on individual organs and systems, and closes with a chapter about anæsthetic explosions.

Dr. Harris's book is outstanding; hence it is difficult to choose any one section for special commendation. The whole is full of valuable information, is thoroughly reliable, and forms an up-to-date guide to the administration of anæsthetics. It will certainly arouse and stimulate much interest among anæsthetists, and is an ideal book for reference, having an extensive bibliography of two hundred and seven references. To the student of anæsthesia (and all anæsthetists are life-long students) this book will prove of considerable value, since the information it contains should to a large extent help to nullify mistakes. For candidates who have yet to obtain the diploma of anæsthesia, this work should prove of very great assistance for Part 1 and Part 2 of [illegible] examination.

H. Roy Bla

SCIENCE AND TRIBAL ART

By WILLIAM FAGG

An exhibition of "Traditional Art from the Colonies", held recently in the Art Gallery of the Imperial Institute, London, was, for the discerning public, an outstanding achievement of the Festival Year, even though it was too modestly advertised; its interest lay not only in the fact that it was the best display of tribal (and especially African) art, selected and arranged as 'art', that has ever been held in Great Britain, but also in the many problems which it offered for solution by scientific disciplines that have no normal connexion with the world of art. I am not now thinking of ethnology and archæology, in which æsthetic studies have, or ought to have, a key place, and which are not sciences in the full sense, but rather of some of the natural sciences, from which important—and perhaps in some cases as yet unsuspected—contributions may be demanded in the next few years.

There is a sense in which all true art—all art, that is to say; which fulfils art's immemorial function of improving upon and 'harmonizing' Nature (in the spirit of the Indo-Aryan root from which both 'art' and 'harmony' are derived)—is, like science itself, inductive. I mean that it proceeds from the particular to the general, beginning from human and other forms and stylizing or generalizing them. It is doubtful whether the *trompe l'œil* schools of art, the photographic realists who aim at nothing more than precise recording of the object, can be called artists at all in any strict sense; some of them, indeed, seek on the contrary to crystallize general ideas in terms of the particular, using purely naturalistic representations to illustrate 'literary' concepts (such as "Love Looked Out") in a manner which we may perhaps erm deductive. The method of true art, as of poetry d music, is surely to bring the mind's centres of ociation into play, and this it does by generalizing ings to a point where the spectator is reminded, subconsciously, of other more-or-less related things. Of all kinds of art none demonstrates this aim more clearly than that of the tribal peoples, among whom disciplined stylization is most highly developed; an ancestor figure from Africa may show not a mere portraiture of the deceased individual's features, but rather an abstraction of some of the qualities which are conventionally attributed to the tribal elders, alive or dead; and this quality of generalization is, of course, also found in the finest classical and renaissance art, transcending the naturalism which is their most obvious characteristic.

A further lesson which may be drawn from such an exhibition as the one at the Imperial Institute is that, whereas in the classical tradition of art only one kind of image, a broadly naturalistic one, is permissible, in tribal art no such single canon can be postulated. The possibilities of stylization are clearly unlimited, and in this exhibition there were well over a hundred different styles, in each of which a whole new world of art has been created, internally coherent and completely convincing even to the uncomprehending Western eye; it is meaningless to try to arrange them in order of artistic value or to suppose that there an be an ideal method of stylization.

he greatest problems involved in the scientific y of tribal art are those concerned with its origins and the historical processes by which it is developed (a task in which study of the social milieu of present-day tribal art is by no means irrelevant). The most obvious way in which the natural and physical sciences can be of use is in the dating of excavated pieces, and here geology is naturally most prominent. In the whole field in which African sculpture is found—a field bounded roughly by the Sahara, the Great Lakes and the Kalahari—the oldest art form to which any date has been assigned on reasonably scientific grounds is the terra-cotta sculpture of which traces have been coming to light during the past eight years around the village of Nok, south of the Central Plateau of Nigeria; the few examples in the exhibition were enough to show that sculpture was in a highly developed state in Northern Nigeria many centuries ago. The pottery figurines, most of them fragmentary, are generally found at a depth of about 25 ft. in alluvial tin-bearing deposits which geologists have recently dated provisionally to the second half of the first millennium B.C. Geological dating is still very difficult in West Africa, whereas in North, East and South Africa elaborate successions have been drawn up with fairly general agreement and are being constantly refined. The dating of the Nok culture is based on a correlation of the deposits in which it is found with the Nakuru Wet Phase of East Africa; but much further pure research in West African geology is needed before the theory can be considered established, and it must also be noted that even a fully successful correlation of East and West African deposits in a geological sense would not necessarily establish synchronism. There is a good prospect that archæology will prove as helpful to geology as geology to archæology.

The great majority of the exhibited sculptures were in wood, and we may note the possibility that dendrochronology, developed with such success in the south-western part of the United States, may be found to work in West Africa also; but little or no study of the formation of tree rings seems to have been carried out there as yet. Simple identifications of the woods used by carvers may, however, be of great value in technological study and also, no doubt, in the identification of styles. It may be worth mentioning that an effort is to be made to test the application of the radiocarbon method of dating to fossil trees found in the Nok deposits with the terra-cotta sculptures.

Metallurgy and chemistry are of particular importance in West African studies because of our dependence on bronze castings for most of our knowledge of art traditions older than about a hundred years (a life span seldom exceeded by wood carvings). The exhibition at the Imperial Institute included some of the most important pieces of bronze and brass work from the Guinea coast, including several of the famous bronze heads from Ife (flown from Nigeria) and representatives of all periods of the related work of Benin, beginning almost certainly before the first arrival of the Portuguese. Already it appears probable that brass (copper alloyed with lead or zinc or both) or virtually pure copper was normally used until the Portuguese introduced the true tin bronze. The opportunity afforded by the brief presence in Britain of these Nigerian treasures has been taken to carry out further scientific research upon them in the research laboratory of the British Museum.

It is now accepted that science has a great part to play in the critical study and treatment of European art; one may instance Dr. H. J. Plenderleith's part in the detection of the van Meegeren forgeries of Vermeer, or the elaborate techniques used in the cleaning of old paintings. Tribal art demands comparable methods: difficulties are involved in the cleaning and preservation of such things as ancient bronzes of superb patination or recent wood-carvings painted in earth colours or infested with woodworm; and forgeries are far from uncommon in the European market (though they are fast being lost to the United States). Science has yet to say the final word on the authenticity of what is probably the most famous of all West African bronzes, the "Olokun" head of Ife in Yorubaland; the results of a preliminary critical examination were given in *Man* of January 1949, and it is hoped that it may soon be sent to England again for a further period of study; meanwhile, it appears to be a skilful replica of the head seen by Frobenius in 1910.

There is, however, one form of scientific investigation—involving biology and applied mathematics—which, so far as I know, has never yet been attempted in the field of tribal art, or probably in any artistic field at all, and one can only briefly mention it in this article. It is concerned with what I may call the mathematical basis of distortion in the interests of art, and for that reason tribal art is clearly the most promising field, and classical art, in which distortion of natural forms is practically excluded, the least promising. There is, indeed, one minor form of European art—caricature—in which distortion and exaggeration play almost as characteristic a part as they do in tribal art; and in the best caricature it would doubtless be found that the exaggerations of a given physiognomy bear a definite and coherent (though not an absolutely precise) mathematical relation to its natural proportions—for example, a politician with a prominent forehead and chin and a somewhat 'dished' profile might find these features carried by the caricaturist's pen to lengths impossible in Nature, and yet, because the relation between the parts remains the same, the distortions render him more rather than less recognizable by the general public. It is possible to express this phenomenon mathematically by means of a series of exponentially curved co-ordinates similar to those employed by Mr. R. Guley Lewis in an article on "Co-ordinates as a Clue to the Morphology of Human Profiles" in *Man* of April 1949 (though that article had no reference to art). The same principles could be profitably applied to much tribal sculpture, in which exponential curves may be found directly represented, besides being followed, unconsciously, in the distortion of other forms. It might be found that the carvers who conformed most closely to D'Arcy Thompson's principles of growth and form were also those recognized as the greatest masters both by their own people and by European critics, and in that case a great step forward in objective criticism would have been taken. I looked forward to some guidance in this connexion when the Institute of Contemporary Arts recently held an exhibition entitled "Growth and Form" and inspired by D'Arcy Thompson's book; but I was disappointed to find that little serious effort had been made to relate his work to the world of art, though it is certainly of great interest that it should be brought to the attention of artists at all. Yet anyone with a scientific as well as an artistic bent who went on from that exhibition to the display of tribal art at the Imperial Institute might well find many a bell rung in his mind by their exotic forms and volumes.

A PHILOSOPHY OF NUTRITION

By Dr. FRANCIS AYLWARD*

Department of Food Technology, Borough Polytechnic, London, S.E.1

On many occasions in recent years attention has been directed to the increasing food requirements of the world following the rapid and continuing growth in population and the desire in all countries for a higher standard of living. The dangers arising from soil erosion have also been stressed, leading as it does to a substantial decline in food production. Several writers have presented a dismal picture of progressive starvation in some regions of the world. Others have adopted a less pessimistic point of view and have suggested that the way to safety lies in an active programme for the efficient conservation and the fuller utilization of the natural resources of the world, together with the development of sparsely populated countries.

In relation to this last point, a question of great importance is whether or not there are sources of foods indigenous to certain countries but perhaps little known in Western Europe or on the North American continent. This is a problem which for the past eight years has been the subject of investigations by Dr. R. H. Harris and his colleagues at the Massachusetts Institute of Technology, who set themselve[illegible] the task of analysing the foods grown and eaten [illegible] Mexico and other countries of Central America. T[illegible] research programme involved: (i) the collect[illegible] and analysis of a large number of edible plants; (ii) the examination of methods of food preparation and the determination of the composition of prepared foods; (iii) a survey of dietary habits; and (iv) a clinical and biochemical investigation of nutritional status.

The work of the Massachusetts group has been characterized by its thoroughness and by the range of analyses carried out over a very wide area; it has already had far-reaching consequences and has led to a new outlook on nutritional problems in the countries concerned. In Mexico City, laboratories have been established at the National Institute of Nutrition for the development of a food analysis programme to be integrated with clinical surveys. Even more striking is the foundation of an Institute of Nutrition of Central America and Panama, an experiment in international co-operation of prime importance in that the central laboratories opened in Guatemala City in 1949 will serve all the countries of the region.

The purpose of the present review is to outline some of the findings of the American group and to relate them to results of investigations in Africa and Asia.

---

*Robert Blair Fellow (1960–51) in the Department of Food T[illegible] nology at the Massachusetts Institute of Technology, Caml[illegible] Mass.

Composition of Indigenous Foods

Mexico and Central America[1]. The collection of food plants in Mexico and Central America was carried out by a botanist, experienced in taxonomy, who obtained more than a thousand samples distributed as follows: Mexico 393; Honduras 200; Guatemala 230; El Salvador 273; Nicaragua 51; Panama 4; Costa Rica 154.

Often several samples of the same species of a plant were collected from different regions in a country, and in the area as a whole there was further duplication which enabled information to be obtained regarding the variations which can occur in the composition of any one plant under different soil and climatic conditions.

One specimen of each plant was placed aside for detailed botanical identification, and full records were made regarding its use as a food. Samples of the edible parts of a second specimen were macerated, treated with suitable preservatives and dispatched by air to the Massachusetts laboratories, where analyses were carried out for moisture, crude fibre, ether extract, nitrogen, phosphorus, calcium, iron, ascorbic acid, thiamine, riboflavin, niacin and vitamin A (as carotene). Control experiments established that no significant quantities of even the most unstable nutrient (ascorbic acid) were lost in the intervals between sampling and analysis.

Many of the plants examined, including species and varieties unknown as food sources in the United States and not previously analysed, were found to contain high levels of certain nutrients (see Table 1). Moreover, varieties of some plants were higher in nutritive value than corresponding varieties grown in the United States. Thus the standard tables of food composition based on plants grown in temperate zones cannot necessarily be used for the calculation of tropical and semi-tropical diets without the possibility of significant errors.

The survey of the composition of crops was extended to include studies of prepared foods and, although these are by no means complete, information of value has already been obtained. Harris[2] has examined the *tortilla*, the 'daily bread' of Mexico which is prepared from Indian corn (maize) by a relatively complicated process. The maize is soaked in a 1 per cent lime suspension and is heated to 80° for twenty to forty-five minutes, after which the mixture is allowed to stand until the following day. The liquid is then decanted off, the maize is washed two or three times with water, the resulting *nixtamal* is finally ground in a mill and the pulverized *masa*, in units of about 50 gm., is shaped into thin cakes and cooked on an iron plate. The original maize and the intermediate and final products were analysed (see Table 2), and it was found that the calcium content of the *tortilla* had increased twenty-fold compared with the original maize, because of the lime treatment.

TABLE 1. COMPARISON OF NUTRITIVE VALUE OF FOOD PLANTS IN CENTRAL AMERICA AND THE UNITED STATES

	Minimum value as basis of comparison (mgm./100 gm.)	No. of food plants above minimum value		No. of Central American food plants above U.S. maximum
		United States	Central America	
Nitrogen	2,500·0	8	20	1
Calcium	100·0	12	29	6
Iron	3·0	19	51	10
Carotene	2·0	14	32	3
Thiamine	0·2	16	42	5
Riboflavin	0·2	13	34	1
Niacin	2·0	13	31	0
Ascorbic acid	75·0	7	48	20

TABLE 2. ANALYSES OF *Tortilla*
Mean values (mgm./100 gm. dry weight)

	Maize	*Nixtamal*	*Tortilla*
Calcium	9	169	190
Phosphorus	275	294	317
Iron	2·7	3·3	3·7
Carotene	0·18	0·15	0·10
Thiamine	0·39	0·35	0·33
Riboflavin	0·09	0·10	0·10
Niacin	1·90	1·80	1·67

The average daily consumption of *tortilla* is of the order of 280 gm. but may be as high as 700 gm., and it is therefore an important source of both calories and minerals, and is a by no means negligible source of some vitamins. Thus these studies provide an interesting demonstration of the importance of local custom and show how false conclusions may be drawn from surveys which do not include methods of food preparation. Another item in the diet of the Mexican Indian is a fermented drink, *pulque*, obtained from a cactus; it provides various minerals and vitamins—especially ascorbic acid. Its use was at one time prohibited; but the resulting illnesses necessitated the removal of the ban[3].

Africa, Asia and Australasia. The activities of the Massachusetts group were extended to China at a stage in the Second World War when it seemed likely that American troops would be stationed there and would require food grown on Chinese soil. Harris[4] was able to demonstrate the high nutritive value of many plants and food preparations analysed.

There is a miscellaneous and not always readily available literature on gardening methods and on plants indigenous to Asia and Africa, and in some cases analyses have been carried out. Yet until recently there was not, perhaps, a sufficient appreciation of the wide variations likely to be found in crops grown in different regions; on the whole, there was a tendency to accept standard Western analyses, and furthermore to regard indigenous foods as of secondary importance.

There were notable exceptions to this attitude, as may be seen from the review of Gangulee[5] and from the work of Aykroyd[6] and his colleagues in India, of Rosedale[7] in Malaya and of Platt[8] in Nyasaland. Abundant evidence of the newer outlook was revealed at the conference of the Nutrition Society on Colonial Problems[9] in March 1946; but at that conference Platt expressed the opinion that the information available on native foods "is approximate and is reasonably satisfactory only for territories largely dependent on imported foods or for those which have more highly developed economies or well-staffed departments of agriculture". On the same occasion, Firth stated how surprised he had been to discover in 1939 that in spite of the excellent surveys in Singapore—extending to 1,000 families—most of these studies were urban; "very little work had been done among the peasants" and "there was not a single full-scale nutritional study in a rural area in Malaya".

Testimony in favour of the importance of native foods has been provided by medical officers who were in prisoner-of-war camps in Asia. Reed has contended that "there is much to be learnt about edible plants which grow easily and the unusual foods which effectively helped to save our lives", and Allen and Scott MacGregor[10] have endorsed this point of view. Stannus[9], from his experience in Africa, has affirmed, "it is not enough to deal only with the main staples and one or two other constituents in the diet. Results are likely to be erroneous unless investigators have an intimate acquaintance with the native and his daily life. Account must be taken of the occasional snack of dried oily fish . . . the fried grasshopper, the raw sugar cane, the assortment of green leaves which the women know so well how to select and cook and, last but not least, the mug of native beer."

During the post-war years, Platt[4] and other members of the staff of the Human Nutritional Unit of the Medical Research Council have stressed the importance of dietary surveys and have published analyses of tropical foods. Parallel action has been taken by Australian workers[11] in New Guinea, and the newer information has been reviewed by Nichols[12]

Nutritional Surveys

The studies of food composition carried out by Harris have been correlated with investigations of the nutritional status of children and adults in Mexico City and elsewhere. One team of workers who had previously conducted surveys in the United States reported that a group of 1,000 poverty-stricken Mexican children showed evidence of a nutritional status superior to that of a group of 760 middle-class children in Michigan, and this surprising conclusion was confirmed by other investigators who examined different age groups in both urban and rural communities. In all cases the incidence of detectable malnutrition was low, although the diets included few, if any, of the ordinary foods common in Europe and the United States[8].

Harris and his colleagues do not suggest that no improvements are necessary; they believe that the people are living on diets which are fairly well balanced in respect to proteins, minerals and vitamins, although the actual amount of food available may be inadequate. 'Balanced starvation' does not necessarily result in the typical histological and biochemical changes indicative of malnutrition; the effects of what has been described as 'hollow hunger' may be seen in the mental outlook of a people, and notably in a disinclination to make physical effort.

The American workers have presented a more optimistic picture of the nutritional state of the people of Mexico than might have been expected; so, too, warnings against excessive pessimism have been given by Stannus[9], who has pointed out that from the bare figures of a nutritional survey in Africa, the whole population in some regions might be expected to be suffering from malnutrition, although observations reveal that this is not so. Cathcart[13] has also suggested the need for a cautious interpretation of the results of surveys, affirming that "any diet can be regarded as defective if you put your standards high enough".

Food and Population

The surveys of diets and nutritional status, taken in conjunction with the laboratory findings of food composition, point to the conclusion that many countries should be able to raise nutritional standards and to promote a positive health policy, on the basis of improvements in agriculture leading to a greater production of certain crops of special value. Harris believes that it is necessary to recognize the importance of dietary patterns which vary from one country to another, and indeed from one area to another in the same country. These patterns are the results of age-old experience and accumulated wisdom, and any drastic and sudden change may lead to widespread malnutrition. Modifications have taken place and perhaps should take place, but any recommendations for changes should be made only with the full knowledge of both the immediate effects and later consequences.

For long periods of time communities have existed and have increased and multiplied without our newer knowledge of nutrition, and dependent almost entirely on indigenous crops and to a lesser extent on animals. The indigenous foods of many areas, when judged by the tests of history and also of vital statistics, must contain within themselves the nutrients essential for growth and reproduction. There may be specific deficiencies in some areas; there may be food shortages because of over-population or crop failure; there may be problems following industrialization and the growth of large towns, but rural communities are usually able to thrive.

It is evident that a distinction must be made between basic nutritional concepts which have universal significance and secondary concepts, such as the primacy of animal proteins and the necessity of milk and orange juice which may not have world-wide application. Certain dietary programmes which may be ideal in Western Europe or in North America may be unsuitable or impossible in other regions. Thus as part of any campaign for improved agriculture in under-developed countries, there must be a plan of education in which the theory of nutrition is taught and also its practice, with the proviso that diets recommended should be based as far as possible on the existing habits of the people rather than chosen from a typical European or American diet sheet.

Much remains to be done in Central America and elsewhere to correlate clinical and laboratory investigations. The establishment of minimum dietary standards for minerals and vitamins in terms of indigenous crops is but one aspect of the programme. Further and more difficult tasks are the determination of the biological values of the proteins available in these crops and the assessment of the relative quantities of fats, carbohydrates and proteins that can be obtained from the sources available and included in a diet of adequate calorie content. Clearly the implementation of a programme on the above lines will involve extensive laboratory work on crops and food products in many regions, and this must be carried out using standard methods and techniques so that the results obtained in different centres may be comparable.

It is good to know that groups of workers, one concerned with the 'good neighbours' south of the United States' border, others concerned with the Asiatic Dominions and the African territories, have by different routes come to somewhat similar conclusions in the recognition of indigenous dietary patterns and of indigenous agriculture as a basis of sound nutrition. When the existing facts are more generally known, if the results are extended and confirmed, if there is a more adequate recognition of the value of mixed proteins from plants, then there may be some recession in that pessimism which has become so common in the consideration of the world's food supply.

OBITUARIES

Prof. C. J. van der Horst

PROF. C. J. VAN DER HORST died in Johannesburg on Oct. 10. He was born in Holland on May 11, 1889, and educated in that country, studying under Profs. Hugo de Vries and Max Weber in the University of Amsterdam. His thesis for the doctorate was on the structure of the brain in fish. On graduation he was appointed chief assistant to Prof. Sluiter in Amsterdam, and there wrote a monograph on the corals of the *Siboga* expedition. He soon returned to neurology, working with Judson Herrick in Chicago, and becoming sub-director of the Institute for Brain Research (Herseninstitut) in Amsterdam in 1925 under its director, the late Prof. C. U. Ariëns Kappers. Van der Horst was thus a zoologist of unusually wide interests and knowledge when he was appointed senior lecturer in zoology in Johannesburg in 1928 under the late Prof. H. B. Fantham. There he soon established a reputation as a man of scientific distinction, of sound judgment, and of great personal charm. Thus it was natural that he should succeed to the chair of zoology in 1932, when Prof. Fantham accepted the chair of zoology in McGill University, Montreal.

In the meantime, van der Horst had turned his attention to the Enteropneusta, soon becoming recognized as the authority on those animals. His review of the group in Bronn's "Tierreich" is an original and lasting contribution to systematic zoology.

Then, at a relatively mature age, following the example of his illustrious fellow-countryman, A. A. W. Hubrecht, van der Horst turned to the study of mammalian embryology and began to collect developmental material of many of the rarer and more interesting South African mammals, gradually building up magnificent collections of the elephant shrew (*Elephantulus*), the golden mole (*Eremitalpa*), *Pedetes* and other forms. The first fruits of this work appeared in a series of papers (1940–46) in collaboration with Dr. J. Gillman, in which the authors elucidated the reproductive cycle of *Elephantulus*, providing detailed descriptions of the ovarian and uterine changes and valuable discussions of the mechanism of ovulation and the history and functional significance of the corpus luteum. They showed that *Elephantulus* far surpasses all other mammals in the number of ova shed at each ovulation (up to 120 or more), and that out of this large number only two eggs become implanted and survive (one in each uterus). In two outstanding papers on the early development of *Elephantulus* (1942, 1943) van der Horst showed that it displays features of very great interest, some of them, indeed, unique; for example, the attainment of a vesicular blastula already in the four-celled stage and the formation of the embryonal knot from amœboid cells detached from the blastocyst wall. In later papers, he described for the first time early stages in the development of the golden mole and the first phases of placental development in the aardvark (*Orycteropus*); and in a highly important paper (1949) he showed that the placenta of the tree-shrew (*Tupaia*) is not hæmo-chorial, as Hubrecht believed, but belongs to the more primitive endothelio-chorial type, a discovery of significance in view of the discussions as to the systematic position of the tree-shrews. His last contribution (1950) provides a detailed account of the placentation of *Elephantulus*, together with an interesting discussion of the relevant literature. The contributions he has made to mammalian embryology show how very greatly we must regret that his work in this field has come to so untimely an end.

Prof. van der Horst's influence on the development of zoology in South Africa has been great; the courses given in his department have presented the subject as a whole, extending far beyond the comparative anatomy which was his own field. Thus, impressed with the impossibility of teaching students who had no access to the sea, van der Horst found an island off Lorenço Marques to which he took students, living in camp and working in a temporary hut. This course proved so successful that a year ago the Portuguese Government built a permanent marine station on the island for the use of the University of Johannesburg, in effect as a tribute to van der Horst himself, an account of which by Mrs. Tattersall will be found in *Nature* of December 1, p. 946. It is to be hoped that the station will be permanently associated with his name.

Prof. van der Horst was one of the kindliest and most generous of men, and his unexpected death will be felt with a deep sense of loss not only by his colleagues in South Africa but also by his many friends in Great Britain and other European countries. He was elected a corresponding member of the Zoological Society of London in 1943, and in 1950 was awarded the Linnean Gold Medal of the Swedish Academy of Science, an honour he greatly appreciated. He was a member of the International Institute of Embryology (1948) and a Foreign Member of the Royal Netherlands Academy (1950) and of the Norwegian Academy of Science (1951). His wife and daughter survive him, and to them we offer our sympathy.

Mr. F. O. Barlow

FRANK OSWELL BARLOW, well known for his casts and restorations of fossil human skulls, died at Merston, Sussex, on November 12. In August 1896, when fifteen years old, he entered the Geological Department of the British Museum (Natural History) as an unpaid learner in the workshop. In 1908 he there succeeded his father as "mason" (as the chief preparator was then called). Caleb Barlow had been in the Museum since 1874, developing, modelling, casting and mounting fossils, mainly vertebrates.

His son carried on the same kind of work with great distinction for forty-five years, until he retired in 1941.

During 1903–4 Mr. Barlow spent a year in the Fayum (Egypt) excavating Cænozoic vertebrates with Dr. C. W. Andrews, and afterwards made restorations of the most important finds, such as *Arsinoitherium*. He developed Sir Arthur Smith Woodward's collection of Pliocene mammal remains from Pikermi, Greece, and many other famous specimens, including *Archæopteryx*. His last major work at the Museum was to carry out the difficult task of restoring the head of the Triassic amphibian *Cyclotosaurus* from mere cavities in the rock.

To the outside world, he was best known for his work in palæoanthropology, and particularly for his modelling of Smith Woodward's restoration of the Piltdown skull. He is one of the figures seen standing behind Sir Arthur Keith in the painting by John Cooke, R.A., illustrating the Piltdown controversy (1913), which now hangs in the rooms of the Geological Society of London. He was not placed on the pensionable staff of the Museum until 1921, and, like his father, he had worked in his spare time with the firm of R. F. Damon and Co., which he eventually took over, and developed on the anthropological side. For many years he provided scientific institutions all over the world with casts of the chief specimens of fossil men, produced with unparalleled skill and fidelity. His stock of moulds has now been taken over by the Wenner-Gren Foundation in order that his work may be continued.

Mr. Barlow will be remembered by all who knew him for his personality, his massively imposing figure, resonant voice and courteous approach. He was a man of wide culture, as his conversation revealed. He had an extensive knowledge of literature and, like his father, he was musical. His rich bass voice was for many years heard in male voice choirs, and he sang at coronations and other special occasions in Westminster Abbey. He spent his last decade in the pleasant half-timbered Old Parsonage at Merston near Chichester.

W. N. Edwards

NEWS and VIEWS

Queen's University of Belfast

At the Queen's University of Belfast three appointments to chairs have recently been made as follows.

Agricultural Botany : Dr. P. A. Linehan

The whole of Dr. P. A. Linehan's working career has been with the Department of Agricultural Botany in Queen's University and with the Botany Division of the Ministry of Agriculture, Northern Ireland; he has held simultaneous appointments in these two bodies, the most recent being reader and head of the Division, respectively. Dr. Linehan was part-time chairman at the Ninth International Seed Testing Congress, held in Washington, D.C., in 1950, and is a member of various technical committees on seed-testing. He was a foundation member, has been honorary treasurer, and is at present a member of the executive committee and editorial board of the British Grassland Society.

Comparative Pathology : Dr. H. G. Lamont, O.B.E.

After being engaged for a number of years in veterinary and pathological research, Dr. H. G. Lamont was appointed in 1931 to be head of both the Veterinary Research and Dairy Bacteriological Divisions of the Ministry of Agriculture, Northern Ireland; at the same time he was made a lecturer in both veterinary science and dairy bacteriology in Queen's University, and in 1947 was promoted to be reader in veterinary science. In 1941 he was awarded the D.Sc. degree of the University for a thesis on "Observations on Aujeszky's Diseases in Northern Ireland", a neurotrophic virus disease of domestic animals. Dr. Lamont is a member of the Agricultural Research Council committee on pig disease, tuberculosis and tuberculin. and mastitis. He was created an O.B.E. in 1950.

Pure Mathematics : Dr. S. Verblunsky

Dr. Samuel Verblunsky goes to the chair of pure mathematics in Queen's University in place of Prof. T. G. Room, who was unable to take up the appointment (see *Nature*, April 21, p. 630). Dr. Verblunsky was born in London and was educated at Magdalene College, Cambridge, where in 1927 he was a Wrangler with distinction in schedule *B*, later becoming a Rayleigh prizeman and Allen scholar of the University. He was for nine years a lecturer at the Manchester College of Technology and then was appointed to a lectureship at Queen's University, being promoted reader in 1950. He is author of a book on "An Introduction to the Theory of Functions of a Real Variable".

Pittsburgh Award of the Pittsburgh Section, American Chemical Society : Dr. W. A. Gruse

The Pittsburgh Section of the American Chemical Society has announced that the Pittsburgh Award for outstanding service to chemistry has been made to Dr. W. A. Gruse, administrative fellow of the Petroleum Refining Fellowship at the Mellon Institute, Pittsburgh. The Award is in recognition of Dr. Gruse's activities as a technical administrator and acknowledged expert in the field of petroleum chemistry, and more particularly for the work of his Fellowship, financed by the Gulf Research and Development Co., which has resulted in fundamental improvements in the refining of petrol, lubricating oil, waxes and other petroleum products. After graduating at Johns Hopkins University and taking his Ph.D. at the University of Wisconsin, Dr. Gruse taught for some years, and then served in the Chemical Warfare Service during the First World War. He became a fellow of the Mellon Institute in 1919 and a senior fellow in 1923, and then in 1945 took up his present appointment at the Institute. During the Second World War he was awarded a Certificate of Merit from the United States Office of Scientific Research and Development, and the Distinguished Service Award of the Ordnance Department. Dr. Gruse has been very active in the American Chemical Society, having been first secretary of the Petroleum Division in 1921, and chairman of the Pittsburgh Section during 1943–44; he is chairman of the Committee on Automotive Engine Oils of the American Society for Testing Materials.

Part-time Work in Chemical Engineering

The would-be chemical engineer is in the unfortunate position of having to acquire a knowledge of the fundamental principles of both chemistry and engineering before he can embark on the application of these principles to the design of plant and the development of processes. This preliminary work cannot be greatly curtailed, and consequently the training of a chemical engineer is bound to take longer than that of a pure chemist or an engineer. The Institution of Chemical Engineers published some years ago a scheme for a full-time degree course in chemical engineering extending over four years; but, in view of the great shortage of chemical engineers, it has been felt for some time that degree courses alone are not sufficient and that a valuable method of increasing the supply of chemical engineers would be the establishment of part-time courses. The difficulty has been to devise such courses without making them of inordinate length. The Institution has now put forward a method of instruction in the form of a pamphlet entitled "Scheme for a Part-time Course in Chemical Engineering" (pp. 23; London: the Institution, 1951; 2s.). This is described, perhaps optimistically, as a three-year course with an "endorsement year" for entrants already holding Ordinary National Certificates in chemistry or mechanical engineering. It is quite clear, however, that the course is really one of four years, as, without the endorsement year, it would be very incomplete; with the endorsement year, the course is admirable and, on paper at least, equivalent to the degree course. Detailed syllabuses and the approximate times spent on each subject are given, which, though only suggestions, will undoubtedly prove of great value to those who are considering the possibilities of such a course. It should be noted that the times given include laboratory work. In addition to the purely formal matter, the pamphlet abounds in brief remarks on the underlying principles of the teaching and the emphasis to be placed on different subjects; it is worth reading for these alone.

Weather Artistry

Three recent articles by L. C. W. Bonacina in the Royal Meteorological Society's monthly periodical *Weather* deal with the picturesque effects of weather, especially cloudscapes. The first, "The Scenery of Devonshire in Relation to Weather and Climate" (May 1951), is a rapid tour through the coastlands, valleys and moors in sunshine, shower, frost, fog and snow. In "London's Picturesque Cloud Scenery" (November 1951) we read how, in the built-up areas of south-east England, man may play havoc with the beauties of hill and woodland, but the sky is ortunately beyond his reach. Even the pearly ondon smoke haze may add to the beauty of altering glints of silvery or golden sunlight seen to rfection as they steal across the Thames". London gs are rather tactfully passed over. The remaining icle, "Turner as a Weather Painter, a Centenary preciation" (July 1951), which is illustrated by oductions of "The Wreck" and "Snowstorm", is ilful analysis of the weather symbolism in Turner's erings of cloud and sea, and the effects of sun- and haze on vistas of mountains. In fact, as Bonacina points out, instantaneous detail of l weather in paint is almost impossible for an to realise; he can only reproduce the spirit of pidly changing scene. Turner's cloudscapes not be perfect meteorology, but they are locent art.

ing Colonial Raw Materials

Colonial Office publication, "The Processing ial Raw Materials", by Charlotte Leubuscher (pp. 186; London: H.M.S.O., 1951; 10s. net), it is pointed out that the root causes why processing industries have not developed in many tropical countries are general economic backwardness and low standards of living. Prospects for the establishment of processing industries are brightest for materials such as oilseeds and cane sugar, which have a local market or where such a market might easily be established. There is less likelihood that processing factories can be successfully established for materials such as cocoa or sisal for which the markets are almost entirely outside the producing countries. Often a producing territory provides too small a basis for the development of an efficient industry. The market in this event would have to be regional, but it does not follow that the most advantageous situation for a processing industry will necessarily be in the country producing the bulk of the raw material. In other words, it is likely that the tendency for industries to be attracted by the markets where their output is sold will assert itself also in the tropics. This is exemplified by the comparatively advanced industrial development of Trinidad within the West Indian region and the industrial importance of Singapore where raw materials from the Malayan hinterland and Indonesia are processed on a large scale.

Soil Survey of Great Britain: Report for 1950

The Soil Survey Research Board of the Agricultural Research Council has recently published report No. 3 of the Soil Survey of Great Britain (pp. 36+3 plates; London: H.M.S.O., 1951; 3s. net). This report summarizes the progress made during 1950 and gives brief descriptions of new series found. It also includes an obituary of Prof. G. W. Robinson, chairman of the Board, who died during the year. The broad classification of previous reports has been retained; this follows current international practice, with subdivisions to take into account differences in drainage and in the rocks from which the soils are formed. The classification is shown by tables, and this should assist in the recognition of soils developed on the same rocks in those parts of Britain which have not yet been mapped. During the year a further 327,000 acres have been surveyed, and work has continued in Lancashire, Yorkshire, Banffshire, Kincardineshire and Angus, Roxburghshire and Ayrshire. The survey of a sheet around Cambridge has been started with the view of obtaining information about the Fenland soils. The sheets covering Anglesey and the Glastonbury (Somerset) sheet have been completed and are being prepared for publication, and the Wem (Shropshire) sheet is in an advanced state of preparation for publication. Soil maps and reports of the north of Banffshire and the north-east of Aberdeenshire are almost ready for printing.

Science Abstracting: Final Report of the Paris International Conference

The final report of the International Conference on Science Abstracting, convened in Paris by the United Nations Educational, Scientific and Cultural Organization during June 20–25, 1949, has now been issued (pp. 192+10 plates. Paris: Unesco; London: H.M.S.O., 1951; 12s. 3d. net) and gives a clear idea of studies and discussions out of which the recommendations of the Final Act of the Conference (see *Nature*, 164, 998; 1949) emerged; the Final Act is given in the appendixes to the report. These appendixes also include, among other documents, the declaration on fair dealing in regard to copying from scientific periodicals and the guide for the preparation of synopses, issued by the Royal Society in April 1949, and the recommendations and resolutions adopted in June 1949 by the Interim Co-ordinating Committee on Medical and Biological Abstracting, as well as a bibliography. The ten chapters of the report review briefly the preliminary report and its preparation; types of abstract and the scope and nature of abstracting services; the authorship of abstracts; methods of publication, including costs, arrangement and the desirability of common bibliographical rules; methods of distribution, including the use of offprints and microfilms and means of reducing the time-lag; the selection of abstracts, including indexing systems and the classifications on which indexing systems are based, and the mechanical selection of documents; language problems and the value of translations; the distribution of articles and abstracts by subject; the co-ordination of abstracting services; and the future organization of science abstracting. The report is thus a useful commentary on the Final Act, indicating the trend of responsible opinion on the question, not merely of abstracting but also of the dissemination of science information in the scientific and technical world generally. It is a reference work which should facilitate understanding of, and co-operation in, a difficult field.

Determination of Earthquake Azimuths from Observations at a Single Station

PROF. W. HILLER, of Stuttgart, in a paper entitled "Über die Bestimmung des Azimuts von Fernbeben aus Oberflächenwellen" (*Gerlands Beiträge zur Geophysik*, 61, Heft 4, 221–231, Leipzig; 1950), has published details of a method of finding the azimuth of an earthquake from observations at one station. Prof. Hiller states that in many earthquakes the *P* waves are only feebly recorded, or indeed may not be recorded at all, so that the determination of azimuth by means of *P* waves is not possible in these cases. In most earthquakes the surface waves are strongly registered. If one has at one's disposal a record of an earthquake on each of three components obtained with instruments having as nearly as possible the same constants, it is possible to find those positions in the surface waves which indicate the arrival at the observatory of pure Love waves or pure Rayleigh waves. The direction of oscillation of the Rayleigh waves is then used to give the azimuth of the epicentre. (In a Rayleigh wave the motion of the earth particle is in the form of an ellipse in the plane containing the vertical and the direction of the earthquake epicentre to the observatory. The motion of the particle in the ellipse is towards the epicentre at the top of the ellipse.) Prof. Hiller has applied this method with success to hundreds of cases in which the seismograms from the Stuttgart Galitzin–Wilip instruments were used; and illustrated examples are given in the paper.

Bibliography of Seismology

Nos. 6, 7 and 8 of Vol. 14 of the Bibliography of Seismology, published by the Dominion Observatory, Ottawa (Ottawa: King's Printer), contain 438 items of pure and applied seismology. The intense interest in microseisms appears to have passed its peak in 1948–49, since in Nos. 5 and 6 of the Bibliography no fewer than twenty-eight items referred to microseism whereas in Nos. 7 and 8 nineteen items were so listed. The mathematical aspects of seismic waves still attract attention, and it appears that a renewed interest in seismographs exists; in Nos. 5 and 6 of the Bibliography nine items were concerned with instruments, whereas in Nos. 7 and 8 twenty items referred to seismographs. There is no doubt that a need is now felt for several instruments designed to work in prescribed conditions and to record particular seismic phenomena, as distinct from one instrument designed to record as many seismic waves as possible. Item 7,407 in the Bibliography refers to one of the latest problems in earthquake waves, namely, "The *T* Phase of Shallow Focus Earthquakes", by Ivan Tolstoy and Maurice Ewing (*Bull. Seis. Soc. America*, 40, No. 1; January 1950). This *T* phase appears to be a feature of submarine earthquakes and may be of use in giving a warning of tsunamis. Recent theoretical work mentioned (Item 7,200) is "On the Nature of the Earth's Interior" by W. H. Ramsey (*Mon. Not. Roy. Astro. Soc., Geophys. Supp.*, 5, No. 9; October 1949) and refers to work on the calculated effects of pressure on the atomic constitution of materials within the earth. In this connexion reference may also be made to Dr. Ramsey's article in *Nature* of October 20, p. 676.

Apia Observatory, Western Samoa: Report for 1941

THE annual report for 1941 of the Apia Observatory, Western Samoa (pp. 170; Wellington, New Zealand: Government Printer, 1950) has only recently been issued. Observations during that year were made in the following geophysical subjects: terrestrial magnetism, seismology, meteorology, atmospheric electricity and tides; details are given in tabular matter or otherwise. Preliminary remarks at the beginning of the various sections describe the instruments and provide other relevant information. Hourly scalings of heights of the tides, automatic recording being made by means of the portable tide-gauge No. 11664, together with times and heights of high and low water, were sent, as usual, each month to the United States Coast and Geodetic Survey in Washington, D.C. The resident staff included the acting director, Mr. H. B. Sapsford, and four professional assistants, and in addition there was a locally recruited staff of ten.

Announcements

PROF. EUGÈNE DARMOIS, professor of physics the University of Paris, has been elected a memb of the General Physics Section of the Paris Acade of Sciences in succession to the late Prof. A Cotton.

IN Memorandum No. 25 of the Medical Rese Council, "The Social Consequences of Pne coniosis among Coalminers in South Wales" Dr. P. Hugh-Jones and Dr. C. M. Fletcher don: H.M. Stationery Office, 1951; 1s. 9d. methods of studying the connexion between and disease and the physiological assessm shortness of breath are discussed. The two dealing with the improvement of human perfo by laboratory studies include a valuable p Sir Frederic Bartlett on the laboratory and human activities, and papers dealing with the of warmth on comfort and efficiency [illegible] studies of the effects of heat and [illegible] in machine design.

UNIVERSITY COLLEGE, SOUTHAMPTON

DEPARTMENT OF ZOOLOGY

PROF. J. Z. YOUNG, professor of anatomy, University College, London, opened the new Department of Zoology at University College, Southampton, on December 5. In an address before the opening ceremony, which was attended by representatives of universities and other bodies, Prof. Young pointed out that although there are many reasons for the study of zoology, the most important is to satisfy our urge to become acquainted with the animals around us. He emphasized the richness of animal life still to be found in the British Isles, and suggested that the great abundance and variety of life in freshwater ponds and streams, and even more especially in the sea, should merit our particular attention. With the importance of the fishing industry in Great Britain, it is clear that the study of marine life is of very considerable practical value. Prof. Young expressed the hope that the new Department would study animals in relation to their environment. At the same time experimental zoology, experimental embryology, anatomy and other methods of approach, he said, are essential to the study of the animal as a whole. In this connexion he welcomed the emphasis which is being placed in the new Department on comparative physiology. Even man and his environment may be regarded as a proper subject (though admittedly a very complex one) for zoologists to study. Thus the zoologist should be prepared to extend his thinking to anthropology and related subjects. But whereas on one side the study of zoology may march with philosophy, on the other hand it is just as needful, if we are to understand the working of animals fully, to enter the fields of biochemistry and biophysics. Zoology is therefore a fundamental science and at the same time an all-embracing subject requiring the most severe mental discipline. He hoped, therefore, that in Southampton zoology would not be too narrowly interpreted. The new and well-equipped laboratories, he said, mark an important step in the development of the subject with which Southampton can make a real contribution to biological studies.

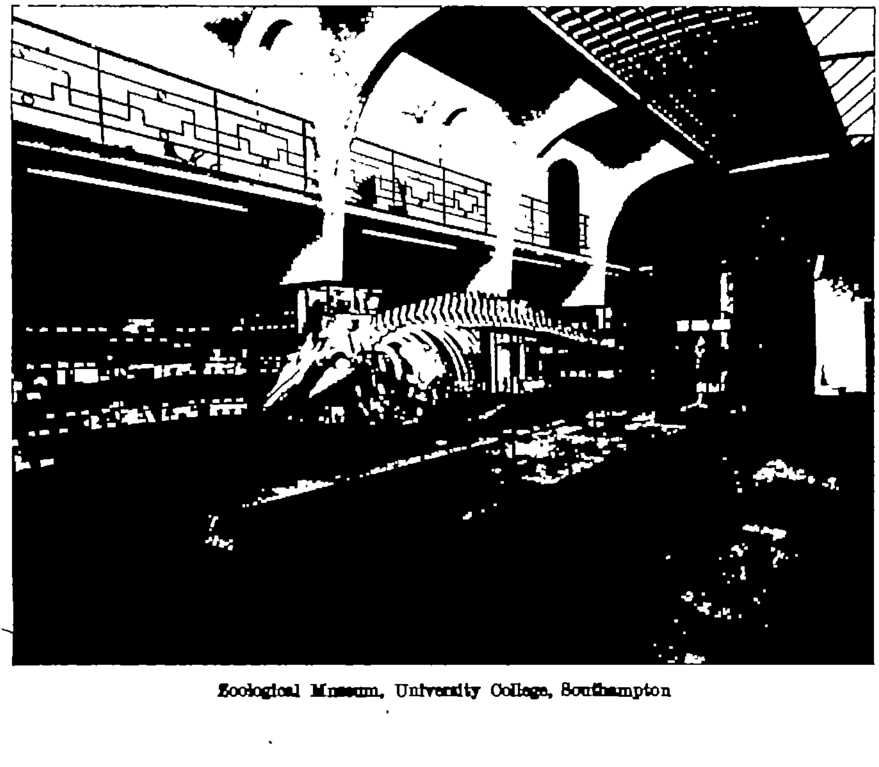
The new Department is a well-designed building of two floors, built of brick, and some 130 ft. long. It has been added to an existing block which once housed both the Geology and Zoology Departments, and between the old and new buildings a new zoological museum has also been erected.

The whole Department has been supplied with teak benching, and care has been taken in planning extensive cupboard, shelf and drawer accommodation. All laboratories and private rooms have been provided with ample electric power points. It has been possible also to provide microscopes, low-power binocular microscopes and general equipment for each laboratory in numbers sufficient to make each almost a self-contained unit.

On the ground floor the new Department houses a well-equipped physiology laboratory. This includes benches designed for kymograph work, as well as chemical and embedding benches and a smoking and fume cupboard. Near by is a dark room reserved for physiological work. Apart from general equipment, the physiology laboratory is furnished with recording apparatus, refrigerators, a Spekker photoelectric absorptiometer, direct-reading balances and a respiration bath.

Across the corridor from the physiology laboratory there is a well-ventilated and lighted animal house with stocks of 'pure line' rats, mice and guinea pigs housed in racks of metal cages. Special heated aquarium sinks also maintain a colony of 250 South African toads (*Xenopus*). These are being used mainly for research on the pituitary and the physiology of colour change. The mammal stocks are used for research into growth hormone, adrenocorticotropic hormone and other endocrine gland effects, and also as stock for teaching purposes. Both the animal house and the nearby preparation room, which is fitted with a large tiled dissecting slab and work bench, have concrete floors to facilitate washing.

There is a cold room of generous proportions which is capable of giving constant temperatures (c. ±0·5) from 0° C. up to room temperature. This is made possible by a large refrigerating unit and a system



Zoological Museum, University College, Southampton of fans and ducts to circulate the cold air. The room is insulated throughout by a double layer of cork, faced with white polished asbestos boarding. Daylight is admitted by a vacuum-insulated window; but the room can rapidly be converted into an experimental dark room with controlled lighting. Three large concrete tanks with heating units have been built into the cold room so that constant-temperature baths at different temperatures can be operated at any one time.

An aquarium room with compressed air supply is also situated on the ground floor. Both the aquarium and cold rooms are already in use for experimental work on marine and freshwater animals. The aquarium room includes two large slate storage tanks for living animals, in addition to the usual small tanks.

The new building is equipped with a departmental photographic dark room and a small developing room. Equipment in the photographic room includes an optical bench with photomicrographic apparatus and an enlarger for both micro-film and ordinary-size negatives.

The ground floor also has three lecturer's rooms, a technician's room, a large research room occupied by two postgraduate students and a room equipped with sterilizing ovens and an autoclave. Store rooms for glassware, chemicals, general equipment and one for nets and other ecological apparatus complete the ground floor. A small lift for goods serves both floors of the building.

On the upper floor, apart from the professor's room, two lecturer's rooms and a research room, there are three laboratories, two of which, planned to accommodate about thirty students each, form part of the old block. The remaining new laboratory has been planned as a 'final honours' room, designed to take a dozen students. Each student has ample bench and cupboard accommodation, and the room has also been fitted with a small lectern and blackboard so that it can be used as a lecture and discussion room.

There is a small lecture theatre, capable of seating some sixty students and fitted with an epidiascope which can be sunk into the lecture bench, and also a departmental library equipped with steel shelving to take about four thousand volumes and with study space for about a dozen students. This library houses the majority of the zoological books in the College, and also includes a good selection of full runs of the more important journals in both zoology and physiology.

The new departmental museum, of modern design, measures some 70 ft. × 35 ft. It is lighted by a glass roof supported by four main reinforced concrete arches spaced along the length of the room. A narrow gallery, with 'Lenscrete' panels in the floor to increase the lighting, runs along three sides of the museum and is reached from the upper floor of the Department. The concrete arches mark off bays at the ground-floor level of the museum, and glass display cases, 7 ft. 6 in. high, framed with Australian walnut and bronze fittings, have been placed around the walls and bays. Heating units have been sunk into the lower parts of the cases.

The sliding glass panels give excellent views of the collections displayed. Both the day lighting and the fluorescent lighting, hidden largely in the glass roofing, have been specially planned to minimize reflexion from the glass of the cases.

The museum collections are arranged phylogenetically and include dissections and skeletal preparations, many of which have been made by students of the Department as part of their course work. Many specimens have also been generously given by other departments and museums. It is hoped that the museum, though designed primarily as a teaching museum for the Department, will also serve as a centre for the colleges and schools in the area, since Southampton lacks a municipal natural history museum.

The gallery has at present only storage cases housing a large part of the smaller specimens used for general class purposes; but it is hoped that further display cases will be added there in the near future.

The centre of the museum is occupied by a few of the larger exhibits, including an 18 ft. long skeleton of the pilot whale, *Globicephala*, which was prepared last year in the Department from one of the specimens stranded on the beaches at Dunbar. While the present collections are mainly systematic and morphological, ecological and other exhibits are planned for the future.

The new Department was viewed by visitors after the opening ceremony, and demonstrations of the research work now in progress were laid out in the lecturer's and research rooms. They included physiological studies on the endocrine glands, studies on the growth of *Mytilus* and the infection of *Mytilicola*, and factors concerned in the hatching and ecology of *Chirocephalus*. Studies on the respiration of marine Copepoda, and of growth of bones in trout, and some ecological investigations on streams and ponds, and on beech-woods were also demonstrated.

The Department emphasizes ecological work, with the sea and the New Forest area (with its varied streams and woodland) only a few miles away. A small boat is operated in Southampton Water by the Department. At the same time, ecological work is combined so far as possible with experimental zoology. The facilities available for comparative physiology have been planned with the aim of developing this subject both as regards teaching and research.

Students also exhibited some of the dissections and preparations and special studies which they have in progress as part of their normal degree work.

BRITISH FOOD MANUFACTURING INDUSTRIES RESEARCH ASSOCIATION

OPENING OF NEW LABORATORIES

LADY ENGLEDOW, wife of Sir Frank Engledow, Drapers' professor of agriculture in the University of Cambridge, on November 8 cut a ceremonial ribbon stretched across the entrance and declared open the fine new laboratories at Leatherhead of the British Food Manufacturing Industries Research Association.

The Association was formed in the beginning of 1947 by the amalgamation of two much older research organizations. Although nominally only in its fifth year, its work, which covers a broad (and ever-widening) field of food processing and preservation, is a continuance of research that has been developed during the past thirty-two years. In 1919, the British Association of Research for the Cocoa, Chocolate, Sugar Confectionery and Jam Trades was formed as the result of the co-operation of manufacturers in these three fields. Premises were fitted out as laboratories in Holloway, and research commenced under the directorship of T. Macara. In 1925 a further group of food manufacturers, mainly concerned with meat and fish products, set up the British Food Manufacturers' Research Association, at the same address and under the same director of research.

The two organizations continued to work in close association, but retaining their separate entities, until 1946, when amalgamation was decided on and plans drawn up for the construction of new laboratory premises at Leatherhead. In the meantime Mr. Macara had retired and had been succeeded as director of research by Dr. L. E. Campbell. At the first general meeting of the new Association, held in March 1947, Sir Frank Engledow was elected president, an office he still holds. The new laboratories were completed towards the end of 1950. Dr. Campbell relinquished his post in May of this year to join the United Nations Food and Agriculture Organization in Rome, and Dr. F. H. Banfield, who had been deputy director since 1948, took over as director of research.

On the opening day and on the day following, the laboratories were open for inspection by members of the Association and those interested in food research. Between four and five hundred visitors attended and studied the exhibits arranged in the laboratories to illustrate the work and scope of the Association. With a floor area of more than 19,000 sq. ft., the building has been planned on modern lines and the laboratories laid out and equipped in a most up-to-date manner. There are general laboratories accommodating teams of laboratory workers, specialized laboratories such as that devoted to micro-biological investigations, a number of small laboratories housing one or two research workers, a large technical laboratory equipped for carrying out a range of factory processes on a small scale, and a spacious library containing some thousand books and ninety periodicals. The staff numbers about sixty, including some thirty graduates.

The work of the Association is balanced to cover the interests of the various groups of member firms. These groups include manufacturers of bakers' prepared materials, cocoa and chocolate, jam, margarine and compound cooking fats, meat and fish products, pickles and sauces, sugar confectionery, and various miscellaneous products, such as jelly tablets, starch and flour preparations, lemon curd, etc. Research being undertaken falls into two main categories: fundamental research, such as the investigations of problems connected with the rancidity of fats, and research into specific problems arising in connexion with particular manufacturing processes.

Of the general apparatus and equipment displayed on the two days that the laboratories were open, mention may be made of the exhibits designed to illustrate the various methods for the estimation of moisture in foods, the recording of the colour of foodstuffs, the measurement of the strength of gels, the measurement of the viscosity of chocolate and the use of refractometers in factory control. Among the demonstrations of application were the determination of air in margarine, the examination of the aerating properties of egg albumen and its substitutes, detection of fermentation in foodstuffs, measurement of particle size with particular reference to particles of sugar in chocolate, and the study of the properties of starch gels and pastes. For the last-mentioned purpose two viscometers were shown, the Shirley consistometer and the corn industries viscometer. Another instrument recently installed is the Unicam photoelectric absorption spectrophotometer with application to the estimation of vitamin A in marine animal liver oils. Other investigations being undertaken by the Association which were fully demonstrated to visitors were those in connexion with the effect of various methods of cooking on the digestibility of meat proteins, the shrinkage of meat and fish pastes in jars, the sedimentation of sauces, the preparation of gelatine from pork rinds, and the corrosion resistance of stainless steels and other alloys to the action of fruit juices, pickling brines and similar products.

In the micro-biological laboratory both the desirable and undesirable activities of micro-organisms in the preparation of manufactured foods are under investigation. Among desirable activities is the part played by bacteria in the curing of bacon in brine, and in the brining of vegetables. The growth of micro-organisms in pickles or canned goods or of mould on jams is, however, clearly undesirable. Strawberries preserved for jam-making in sulphur dioxide are sometimes subject to a breakdown as the result of the activity of enzymes, and investigation into the exact nature of this action is a subject of research.

A short account of the work of the Association would not be complete without mention of some of its other manifold activities. The suitability of fruits for commercial jam manufacture is one important item, and samples of jam prepared in the laboratories were displayed for inspection by visitors. In the entomological laboratory the means for the identification and control of pests liable to infect raw materials are under continual review, as are the methods of controlling rodents.

Analysis of foodstuffs plays a most important part in food manufacture. The extensive laboratory at Leatherhead devoted to this purpose is fully engaged in the testing of new official methods and the development of methods of analysis suitable for routine factory control. The part played by the Association in assisting members to conform to the standards demanded by modern conceptions of purity in foods, and with the food laws of the countries to which their goods are exported, is of the greatest help to members.

GEOLOGY AND MINERAL RESOURCES IN THE BRITISH COLONIES

THE first number of the second volume of the quarterly bulletin issued by the Mineral Resources Division, Colonial Geological Surveys, which has recently been published by H.M. Stationery Office, gives further evidence of the valuable work being done by the expanded Geological Surveys of the Crown Colonies, and of the advantages gained from the limited measure of central organization which came into being after the Second World War.

Much space in this volume is devoted to an article on Sierra Leone, by J. D. Pollett, director of the Geological Survey Department of the Colony. The benefits of government-sponsored geological investigation are here illustrated particularly well. Although the first survey of the Colony, during 1918–21, failed to find any minerals of economic value, the investigations by Dr. N. R. Junner while director from 1928 onwards revealed high-grade iron ore, industrial diamond deposits, chromite, ilmenite and alluvial gold. Of these the first two mentioned have now reached major importance, more than 11,000,000 tons of hæmatite and 10,000,000 carats of diamonds having been exported during 1930–49.

Sierra Leone is mainly underlain by rocks of Pre-Cambrian age, of which approximately half the total area is granite. This is intrusive into metamorphic rocks, the schists, gneisses and granulites of the Kasila Series, the Kambui Schists and the Marampa Schists. The granite is overlain by folded unfossiliferous sediments, the Rokell River Series, and these in their turn are covered unconformably with bedded arenaceous rocks believed to be equivalent to Grès Horizonteaux of French Guinea, where fossil evidence indicates a Middle Silurian age. The primary iron-ore deposits consist of schistose specular hæmatite in the Marampa Schists, and banded iron-formation in the Kambui Schists. Near the surface, intense lateritic weathering has produced dense secondary hæmatite. The Colony peninsula is underlain by a banded noritic complex, including troctolite and gabbros, apparently lopolithic in form, and having other features in common with the great Bushveld lopolith in South Africa, including the presence of platinum.

Maps showing the geology and distribution of mineral localities on a scale of 1 : 1,000,000 accompany Mr. Pollett's article. Surveying of the Colony on the 1 inch : 1 mile scale has now begun with the expanded staff made possible by a grant from the Colonial Development and Welfare Scheme.

Under "Notes and Abstracts" an account is given of one of the first results of the recent effort to interest home university geological workers in Great Britain in problems of Colonial geology. A visit by Drs. J. Sutton and Janet Watson to Tanganyika to examine the granites and basement rocks is described in some detail; Prof. W. Q. Kennedy visited Uganda.

The issue also includes articles on British Somaliland and on photogeology, and a laboratory report on glass sand from Nigeria. Reports from the various Geological Survey units indicate that geological work of considerable scientific interest as well as economic value is in progress in many parts of British Colonial territories.

K. C. DUNHAM

PALATABILITY OF BIRDS' EGGS

IN a paper submitted to the Zoological Society of London (*Proc. Zool. Soc. Lond.*, 121, Part I), Dr. Hugh Cott describes the results of an investigation into the relative acceptability of the eggs of twenty-five species of birds, belonging to ten orders, as illustrated by the feeding preferences of the hedgehog (*Erinaceus europæus*). In each of 332 experiments, one of four animals used as tasters was presented with a choice between two egg-samples. Possible disturbing factors such as differences in egg-size or shell-coloration, and those due to spatial arrangements of the samples, were eliminated by the use of raw egg, offered in equal quantities, and by the successive reversal in position of the egg-species matched within a particular group of experiments, or as offered to a particular experimental animal.

The reliability of the experimental method and the degree of consistency of hedgehog discrimination was checked by repetition experiments (between the same species-pair), both for the same and for different individuals; and by linking and overlapping experiments (between pairs of egg-species more or less widely separated in the edibility series). In general, the results show the hedgehog to be sensitive to differences in the relative palatability of the eggs offered, and to be consistent in its preferences and aversions; these show a broad agreement with those of man for the egg-species considered.

The experiments, which fall into groups carried out with sixty species-pairs, afford a basis for the arrangement of the several species in a provisional hierarchy of preference. The species fall broadly into three grades, and in descending order of acceptability are as follows: (*a*) palatable—kittiwake, eider, razorbill, gannet, domestic fowl, lapwing, common tern, coot; (*b*) intermediate—wood-pigeon, little owl, rook, puffin, magpie, jackdaw, hobby, kestrel, little grebe, buzzard, arctic tern, ringed plover; (*c*) distasteful—blackbird, chaffinch, sedge-warbler, whitethroat, linnet.

It is believed that the preferences shown by hedgehogs are likely to correspond with those of other egg-eating animals, and that, within the limits of the series examined, they afford a satisfactory basis for consideration of the data in general terms. The wide range in specific edibility rating found to occur within certain orders suggests that relative acceptability may be largely independent of systematic status; however, the low mean edibility rating for passeriform species indicates a trend towards nauseousness within this order. No close or obvious connexion has been traced between relative acceptability of the egg and feeding habits of the parent; nor is the quality of the egg at all constantly related to that of the flesh in the species examined.

Yet the experimental results also point towards correlations between relative acceptability and various other ecological factors likely to influence susceptibility to attack by predators. First, there is a broad direct relationship between palatability of the egg and size of the parent. Secondly, the distribution, in terms of acceptability, of species having colonial and solitary nesting habits, respectively, shows a marked tendency for eggs of the former to be more, and those of the latter to be less, palatable. Thirdly, consideration of egg-palatability in relation to nest-site indicates that eggs laid in open nests in moderate growth or low herbage may be relatively distasteful as compared with those laid in various other situations. Fourthly, a general correlation is shown to exist between coloration of the shell and palatability of its contents. Broadly, cryptic eggs tend to belong to the higher edibility grades and distinctively marked eggs to the lower edibility grades.

Cott has also assessed the several species in terms of relative vulnerability, account being taken of such factors as size, weapons of defence, powers of offence, availability of the clutch, general habits, sociability and coloration. A general inverse correlation is shown to exist between the degree of vulnerability and that of acceptability—the most palatable eggs being those laid by non-vulnerable species, the most nauseous by those that are (otherwise) highly vulnerable. It is suggested that the facts point towards an adaptive interpretation of distastefulness in eggs, considered as a deterrent to attack; and that the distinctive coloration of nauseous, but otherwise vulnerable, eggs may have a warning or recognitional value in relation to potential predators.

may be inferred, therefore, that it was less common in the British Isles, though there are enough contemporary references to show that some centuries ago quails were much more numerous and widespread here than they are now.

Towards the end of the twelfth century, for example, Giraldus Cambrensis reported "coturnices hic plurimi" in Ireland. In fifteenth-century literature the term "bevy of quails" occurs repeatedly. In 1466 quails (a hundred dozen) figured in the banquet given for Archbishop Nevill of York at Cawood, and in 1422 quails were included in the coronation feast of Henry VI.

In the sixteenth and seventeenth centuries significant references to quails are numerous: none of the English game-laws (eight up to 1714) mentions quail. But the birds were evidently an esteemed article of diet, and it may be inferred that up to 1700 the quail was a familiar bird in both Great Britain and Ireland and was usually regarded as rather a speciality for the table and probably diminishing, but still plentiful enough to be worth the bird-catcher's attention.

There are remarkably few direct references to the quail in the eighteenth century; but it is doubtful whether it diminished much. At the beginning Morton noted that "it comes into the sandy and warmer soil" of western Northants "at least a fortnight before it settles in the colder clayey part of the county".

There was undoubtedly a marked and progressive decline of quail in Britain in the first half of the nineteenth century; but this was accompanied by a marked increase in Ireland about 1845–50, when several nests could be found in one field. The subsequent decline, perhaps delayed until about 1865, was so marked that by the 1880's quail had almost totally disappeared from Ireland.

In 1865 More assessed the status of quail in Britain on the basis of questionnaires and concluded that "there are few counties in which the quail is considered to breed annually". In the remaining counties of Great Britain the quail was classed as "occasional". It seems that by about 1865 the quail in England had reached nearly the low ebb to which it fell in the twentieth century except for an occasional 'good' year.

To-day, systematic bird reports are produced annually for nearly thirty English counties. Quail records in these reports can be supplemented from the occasional county avifauna and from other records. These figures show that 1936 was the worst year in the twentieth century, the next worst being 1935 and 1940. Except for 1946 every year from 1944 onwards shows a more widespread recording of quail than any year before 1944.

In the present century there have been in the British Isles no quail years so outstanding as 1870 and 1893; but, allowing for various factors, it is probably true that at least twice as many quail visited Britain in 1947 as in any other year this century. 1947 was also a peak year in Belgium, Switzerland, Sweden and Holland.

Most of the records of quail in Britain are from areas of chalk, greensand and oolite. Of the eight most favoured counties six are dominated by these formations, and in them, as in Yorkshire, a very high proportion of the localities named in the quail records are calcareous. It is doubtful how far this correlation is due to preference for these soils and how far to preference for associated land-use.

Throughout its range the quail is a bird of open country, frequenting annual herbaceous growth, so that the deforestation of Europe must greatly have increased the area the bird can inhabit. There has been conflict of opinion about the effect of the subsequent agriculture. For example, in Norfolk the bird was said to like "rough fens", and its nineteenth-century decline has been attributed to the break-up of "coarse tussocky land". Others take the view that the decline of the quail was associated with "the great reduction in acreage of arable". Certainly the increase in quail since 1942 has accompanied a great increase in arable; but it must be recalled that in the first half of the nineteenth century, when arable was expanding in both Great Britain and Ireland, the quail was declining in the former as markedly as it was increasing in the latter.

While some have thought that clover fields are the favourite habitat of the quail, most observers believe that corn-fields are most frequented. Corn has been given as the quail's first preference in Germany, in Savoy and in Holland.

In Britain the prevalence of quail in corn as compared with other crops is likely to be accentuated by modern developments. On one hand the practices of grass-drying and silage-making lead to earlier cutting of some of the forage crops: on the other hand, increase in autumn-sowing of corn results in a bigger proportion of the area under corn being able to offer adequate cover to quail as soon as they arrive.

It is doubtful whether the decline of the quail population in the British Isles, which had to some extent a parallel in Western Europe as a whole, was due to changes in agricultural methods and in particular to the introduction of the mowing machine; human predation has probably been the most important factor in the decline of the quail population. Up to a few years ago exploitation on both sides of the Mediterranean was merciless in both spring and autumn, and the birds were not even left alone during the breeding-season. From Egypt alone, as late as 1913, 1,858,000 quail were exported; with a general fall in the quail population the Egyptian exports in the years 1930–34 varied between 285,000 and 580,000, more than half the birds being captured as they were travelling north to breed. In 1937, import of live quail earlier than July was prohibited in both the main consuming countries, France and Britain, and the spring taking of quail was prohibited in both Egypt and French North Africa. The traffic in quail stopped in 1939 on the outbreak of war and has not been resumed.

Protection of quail visiting Britain has been inadequate and illogical. A hundred years ago, the stock had already been so reduced that no more should have been shot. Yet the quail still can be shot during the close season by owners and occupiers of land on their own land in nearly half the counties of England, including Berkshire, Cambridgeshire, Gloucestershire and Wiltshire, four of the seven counties in which quail are most likely to occur. The proposed new bird-protection legislation should stop these anomalies.

Moreau also discusses certain problems of quail biology and shows that information on the life-history of the quail is full of gaps and of conflicting information. In particular, investigation is needed into the relations of the sexes; it seems probable that mated males call little and that polygamy cannot be the rule. Though considerable attention has been given to the subject of the migration of the quail, it is far from being understood.

Statistical Methods in Anthropology

IN their interesting letter in *Nature*[1] on statistical methods in anthropology, Dr. J. Bronowski and Mr. W. M. Long suggest that the reason why Prof. Zuckerman's findings were at odds with those based on classical comparisons was that he had compared each measurement separately instead of using the comprehensive test provided by the discriminant function. They took as an example the discriminant function calculated from measurements on forty human and forty-four chimpanzee lower milk canines. This gave a wide separation in the ranges of the two groups and conclusively indicated (*a*) that the Kromdraai and Taungs milk canines are not those of chimpanzees and (*b*) that they fall within the human range.

As it appeared to us unlikely (though not, of course, impossible) that a discriminant function would reveal such a distinct separation when a comparison of the individual measurements gave no indication of differences, we asked Prof. Zuckerman if he could furnish us with his measurements on this tooth. These consisted of four measurements, the labial height (H_1), the lingual height (H_2), the maximum anterior-posterior dimension (L), and the labial-lingual breadth (B), on twenty human teeth and twenty-seven chimpanzee teeth, together with data for four fossil lower canine milk teeth for each of which two or three of the above measurements were available.

A full analysis of these data was performed, calculating discriminant functions on all combinations of two, three and all four of the measurements. The results of this analysis are shown in condensed form in the accompanying table, with the exception that measurement H_2 has been omitted, since it was not available for any of the fossils. The first column of the table shows the measurements on which the discrimination is based, and the second the separation of the groups in terms of the mean difference d divided by the estimate of the standard deviation of a single individual within groups s, a plus sign indicating that the chimpanzee has the larger mean measurement or function. The remaining columns show the differences d_1 and d_2, divided by s, of each specimen from the means of man and chimpanzee respectively. If errors in the population means, variances and covariances are ignored, values of d_1/s or d_2/s greater than 1·96 or 2·58 indicate probabilities of less than 1 in 20 or 1 in 100 that the specimen belongs to that group on the evidence of that measurement or function. Errors in the means, etc., may here be substantial, but are progressively reduced as the amount of basic data is increased.

It will be seen that all three measurements for *Paranthropus robustus* (the Kromdraai skull) are similar to those of man, but are significantly different from those of the chimpanzee. For *Paranthropus crassidens* both measurements are similar to those of man, and the B measurement is very significantly different from that of the chimpanzee. We may therefore conclude that these teeth are definitely not those of chimpanzees, and resemble those of man, at any rate in these measurements. The measurements of *Plesianthropus transvaalensis* are close to those of the chimpanzee, but the differences from those of man are not fully significant. In all these cases the values of the discriminant functions merely confirm these findings. For *Australopithecus africanus* (the Taungs skull) the discriminant function indicates a close similarity to man, whereas the L measurement shows an almost significant divergence, suggesting in conjunction with the B measurement that the specimen may belong to neither group.

This last specimen provides an example of an important point which has not been mentioned by Bronowski and Long, and which is quite distinct from their point about fakes. A discriminant function, as its name implies, is designed to enable objects known to belong to one of two groups to be assigned to the correct group. If used for classifying an object that does not belong to either group, it may erroneously indicate that the object belongs to one of the groups, whereas other evidence from the measurements may show quite conclusively that this is not the case. An examination of the value of each individual measurement of the object to be classified in relation to the means and standard deviations of the corresponding measurement for the two groups is an essential first step in avoiding errors of this kind.

In our example, H_1 is the best single measurement for discrimination. If we have a collection of specimens which, in fact, belong to one or other of the groups and rely on this one measurement, it will classify 69 per cent at the 1 in 20 level (43 per cent at the 1 in 100 level), leaving the remainder in doubt, while the discriminant function on H_1 and B will classify 85 per cent and 63 per cent respectively. If those which are doubtful are assigned to one [illegible]other group, depending on which mean is the cl[illegible] the percentage misclassification will be 14 per[illegible]ing H_1 alone and 9 per cent using H_1 and [illegible]e-maining variates, H_2 and L, give a negligible incre[illegible]e in power of discrimination.

The power of discrimination between man and chimpanzee revealed by these results is much less than that obtained by Bronowski and Long from their data. It is clear from the diagrams published in the communication in *Nature* from Le Gros Clark[2] that it is the combination of the two anterior-posterior measurements used by Bronowski and Long which gives the very sharp discrimination, due to the difference in form of the two groups of teeth. It is very probable that a comparison based on the

The molecular relationship between the breakdown of hæmoglobin and the production of carbon monoxide that would be expected from this hypothesis can, in fact, be demonstrated experimentally. The amount of carbon monoxide exhaled per day by a subject was calculated from repeated determinations of the concentration of carbon monoxide in the expired air during several days, and from the average respiratory volume. This came to 6·8 mgm. carbon monoxide per day, while an approximate estimation of the amount of hæmoglobin broken down in one day (calculated from the total hæmoglobin and an average life-span of the erythrocytes of 120 days) was 4 gm. The relation between these values is 1 : 590, while the relation between the molecular weights of carbon monoxide and of hæmoglobin is 1 : 600, if the latter is calculated for each hæmin group.

The endogenous formation of carbon monoxide and its relation with hæmolysis and internal hæmorrhage[4] may be explained on the assumption that carbon monoxide is liberated in connexion with the *intra vital* breakdown of hæmoglobin.

A detailed account of these investigations will be published in *Acta physiologica Scandinavica.*

Enzymatic Conversion of the Stereoisomers of *Iso*Leucine to the Corresponding α-Keto-Acids

THE optical isomers of α-keto-β-methylvaleric [illegible] have been prepared by enzymatic oxidation of [illegible] corresponding D-amino-acids[1]. The keto-acid [illegible]rs (and their 2,4-dinitrophenylhydrazones) pre-[illegible] by enzymatic oxidation of D-*iso*leucine and [illegible]o*iso*leucine exhibited optical rotations which [illegible]e equal in magnitude and opposite in direction[1,2]. Furthermore, from microbiological studies (to be reported in detail elsewhere), a purity of at least 98 per cent may be assigned to the lævorotatory isomer of α-keto-β-methylvaleric acid prepared by enzymatic oxidation of D-*iso*leucine. These findings indicate that the configuration about the β-carbon atom is not measurably altered by enzymatic oxidation of the D-amino-acids or during isolation of the keto-acid.

It has now been found that oxidation of the L-isomers of *iso*leucine and allo*iso*leucine by L-amino-acid oxidase of snake venom, or transamination between these amino-acid isomers and α-ketoglutaric acid catalysed by a soluble hog's heart preparation, leads to similar results, that is, formation of optically active keto-acid isomers which have been isolated as the 2,4-dinitrophenylhydrazones. The experiments with snake venom oxidase were carried out essentially as described for those with D-amino-acid oxidase, except that crystalline beef liver catalase was added to prevent further oxidation of the keto-acids. In the transamination reactions, which did not go to completion, the α-keto-β-methylvaleric acid formed and the residual α-ketoglutaric acid were precipitated by addition of 2,4-dinitrophenylhydrazine. The hydrazones of α-keto-β-methylvaleric acid and α-ketoglutaric acid were separated by counter-current distribution using ethyl acetate and aqueous sodium carbonate as the solvents. The hydrazones were recrystallized from water, dried, and characterized by nitrogen analysis and melting point. The specific optical rotations of the 2,4-dinitrophenylhydrazones of α-keto-β-methylvaleric acids formed by enzymatic action from the four isomers of *iso*leucine are given in the accompanying table; within experimental error, the values are in good agreement.

ENZYMATIC FORMATION OF α-KETO-β-METHYLVALERIC ACIDS FROM FOUR ISOMERS OF *iso*LEUCINE

Substrate	Enzyme	$[\alpha]_D^{26}$ of resulting keto-acid hydrazone*
D-*iso*Leucine	D-Amino-acid oxidase†	− 16 7°
L-*iso*Leucine	L-Amino-acid oxidase‡	+ 17·3°
L-*iso*Leucine + α-ketoglutarate	Transaminase§	+ 16·7°
D-allo*iso*Leucine	D-Amino-acid oxidase	+ 16 7°
L-allo*iso*Leucine	L-Amino-acid oxidase	− 17·1°
L-allo*iso*Leucine + α-ketoglutarate	Transaminase	− 16 4°

* Specific rotation of the 2,4-dinitrophenylhydrazone of α-keto-β-methylvaleric acid (2 per cent solution in ethanol; 2 dm. tube).
† Hog's kidney acetone powder extract.
‡ *Crotalus adamanteus* venom.
§ Prepared from hog's heart.

These results demonstrate that the optical configuration about the β-carbon atom of the four isomers of *iso*leucine is maintained during enzymatic oxidation and transamination, and that a reversible α-β-unsaturation leading to loss of asymmetry at the β-carbon does not occur. However, the possibility is not excluded that reversible α-β-unsaturation may be enzymatically directed so as to preserve the configuration of the β-carbon atom.

Transmission of Natural and Synthetic Mica in the Ultra-Violet

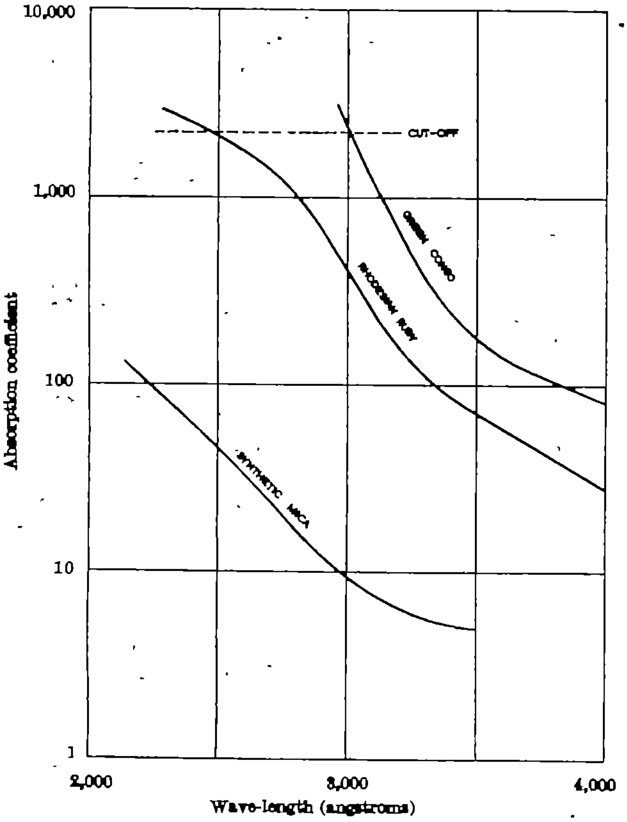
THE various minerals belonging to the mica group are all characterized by the ease with which they cleave. The reason for this behaviour is found in their structure, which consists in all cases of a double sheet of linked silicon – oxygen tetrahedra of the hexagonal type $(Si_4O_{10})^1$. One in every four silicon ions is replaced by aluminium in most of the natural occurring micas (phlogopite, muscovite, biotite), thus giving the basic $AlSi_3O_{10}$ units; these are firmly bound by the incorporation of aluminium, magnesium and iron ions and hydroxyl groups. The double sheets are weakly linked by potassium ions, and it is along this plane that cleavage takes place. The most important micas conform to the idealized formulæ:

Muscovite	$KAl_2(AlSi_3O_{10})(OH)_2$
Phlogopite	$KMg_3(AlSi_3O_{10})(OH)_2$,

but a multitude of substitutions can take place; for example, the magnesium can to some extent be replaced by iron, which gives biotite:

$$K(MgFe)_3(AlSi_3O_{10})(OH)_2.$$

Attempts to synthetize mica were first made more than fifty years ago, but it has been difficult to grow



large crystals. The best results to date appear to have been achieved with synthetic phlogopite, where the hydroxyl group has been replaced by fluorine, that is, $KMg_3AlSi_3O_{10}F_2$[2].

Little information is available on the transmission of natural mica in the ultra-violet[3]. Hausman and Krumpell state that the limit of transmission is 2900 A. and that the green variety absorbs highly, ruby mica least. Transmission measurements have been carried out in this Laboratory on a number of samples of natural micas of different origin, all of which had a very high transmission in the visible region, and also on a water-clear sample of fluorine phlogopite, kindly lent to us by Dr. Middel. The absorption coefficient μ ($I/I_0 = \exp - \mu l$, where I_0 is incident beam, I is transmitted beam, l is thickness in cm.) is shown in the accompanying graph for samples of green Congo, Rhodesian ruby and synthetic mica; due allowance has been made for reflexion losses. These measurements show that the absorption of synthetic mica is much less than that of the natural mica available. This may possibly be ascribed to the low iron content (less than 0·05 per cent) of the synthetic mica we investigated, and, in fact, analysis of the iron content of the samples of natural mica confirmed that the absorption coefficient at 3000 A. was approximately proportional to the iron content. This difference in iron content would also account for the higher ultra-violet absorption of the green variety.

Mica sheets of 10–20 microns thickness are strong enough to be used for windows in vacuum tubes, and vacuum-tight seals both to glass and chrome-iron metal can be made by a simple method[4].

The horizontal line drawn in the graph shows the short-wave cut-off based on a thickness of 10 microns and 10 per cent transmission; for Rhodesian ruby and green Congo mica the limits are respectively 2500 A. and 3000 A. Synthetic mica transmits well below 2000 A.

Synthetic mica can be used, therefor[illegible] a window material with high ultra-violet tra[illegible]ission for vacuum devices such as photocells, el[illegible]ron multipliers, Geiger–Müller counters, ther[illegible]piles, etc. Devices with such windows can be used [illegible] processed at very high temperatures, since the sy[illegible]hetic mica will stand temperatures greater than 1,0[illegible]° C. without deterioration, compared with the t[illegible]perature limitation of muscovite at about 500° C. a[illegible] phlogopite at 800° C.

I wish to thank Mr. J. A. M. van Mo[illegible] and the Directors of Philips Electrical, Ltd., for per[illegible]ission to publish this communication.

Standing Waves in Low-Energy Electron Beams

IN some work here on the focusing of rotational[illegible] symmetrical electron beams in the energy-rang[illegible] 20–70 volts, we have come across cases of standing wave patterns in the electron emission from th[illegible] cathode which may be of interest to valve designe[illegible] and others working on the properties of low-ene[illegible] electron beams.

In the case of 'normal' beam formation [illegible] electron distribution over the cross-section as re[illegible] by a scanned slit arrangement is usually a sm[illegible] curve having a peak current density on the axis[illegible] falling continuously with distance from the axis [illegible] the way to the periphery of the beam. It generally has a Gaussian form.

At low energies, however, there are marked changes. Here, the current to a series of concentric collectors placed transversely at some fixed distance from the emitter, while showing a smooth curve over the cross-section, has a core which appears to approximate to Gaussian form, whereas the tail exhibits a more or less uniform distribution over a considerable portion of its length.

The simple space-charge theory determined by the constancy of the space-charge factor ($V^{3/4}/I^{1/2}$) is found to break down under the following conditions: (*a*) energies less than 20 volts; or (*b*) high emission densities. Both these are connected with effects in the 'virtual' cathode, for example, potential depression. There appears to be an optimum cathode temperature which controls the emission density for both 'semi-hollow' and 'hollow' beams, that is, for those in which the axial emission is less than that off the axis, and where it is practically zero, respectively. The conditions in the 'virtual' cathode are significantly changed by alteration in temperature, which alters emission density, emitting area and initial electron velocity. Fig. 1 shows how the current in the

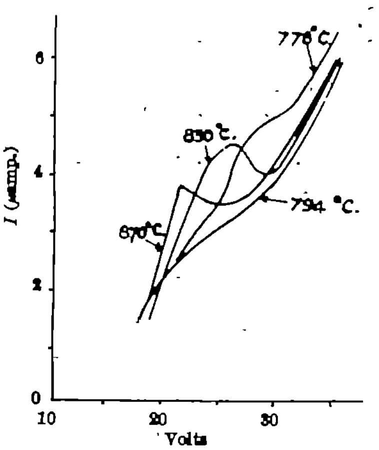

Fig. 1

peripheral region of the beam varies with energy at different temperatures. The total emission characteristic also contained small portions of reverse slope between 20 and 30 volts, which were detected by consecutive measurements at voltages very close together—and were repeatable. The remarkable changes of slope in the 20–30-volt region appear to be connected with changes of state in the cathode emission for particular fields, or to corresponding changes in charge density in the virtual cathode. In fact, the explanation for this kind of anomalous behaviour is much on the same lines as that given by Klemperer[1] from his observations on the splitting of high-energy electron pencils into 'elementaries'. These he attributed to standing-wave patterns in the space charge near the cathode. He quotes C. S. Bull for the suggestion that oscillations set up in the space charge might react on the cathode emission by producing regions of high and low intensity over the emitting surface, and, in fact, this is found to be so on a simple interpretation of the distribution patterns shown in Fig. 2, for a series of energies from 18 to 24 volts. At a higher accelerating voltage ($V = 30$) the current density falls away smoothly from a maximum on the axis.

The periodic character of the fluctuations in emission over the surface is consistent with the assumption that standing waves are present in the space charge. Their formation depends critically on changes in energy over a limited energy-range of about 10 volts. Inside this range, the conditions which make the centre of the cathode either a node or an antinode are extremely sensitive to energy variations—a difference of 2 volts is sufficient to change from one type to the other, as is clear from the graph. The wave-length appears to be of the order of 0·1 mm.

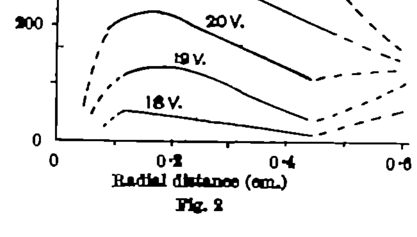

Fig. 2

It is interesting to record that one of us (L. J.) found a similar 'abstraction' of current in a high-energy beam (2 kV.), produced by a conventional electron gun, when certain field conditions were introduced.

It is hoped to publish fuller details of this work in due course.

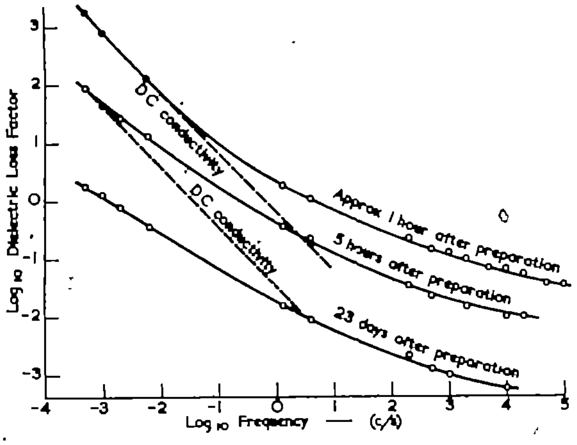
Low-Frequency Dielectric Absorption and Direct-Current Conductivity in Quinol

The large dielectric absorption at low frequencies recently observed[1] in crystalline long-chain alcohols has been shown to be probably due to a hydrogen bonding of the hydroxyl groups to form chains. Hydrogen-bonded hydroxyl groups are also present in the dihydric phenol quinol, according to a structure proposed from X-ray crystallographic data[2], but in this case the hydrogen bonds form regular hexagons. With such a structure the resultant dipole moment should be zero and the compound should give no dielectric absorption. However, in recent measurements in this laboratory, considerable low-frequency absorption was observed in three samples of quinol crystallized from water, ethanol and methanol respectively. This absorption decreased with time of storage at room temperature, as shown in the graph (p. 1122) of the results for the sample crystallized from water. The curves are similar in shape to those obtained previously for *n*-hexadecyl alcohol[3], in which the dielectric absorption was attributed to the presence of extensive hydrogen-bond chains, and it seems likely that the results for quinol can be similarly explained.

Measurements with samples prepared at different intervals from the same batch of crystals gave results similar to those shown in the diagram. This suggested that the absorption may not have been present originally in the crystalline quinol, but resulted from the preparation of the sample for measurement. In this process the crystals were ground to a fine powder and then pressed at about 10,000 lb. per sq. in. to form disks. Experiments on the effect of re-grinding and re-pressing aged disks indicated that it was the grinding process which led to the dielectric absorption.

To explain these results, it is suggested that the grinding causes a partial breakdown of the crystal structure followed by a rearrangement in which hydrogen-bond chains are formed. These give rise to the large dielectric absorption. Also this hydrogen-bond chain structure is unstable in quinol and in time reverts to the hexagon formations of the original crystal, with a consequent decrease in the dielectric absorption.



Dielectric absorption at 20° C. in quinol crystallized from water

Evidence that structural breakdown of quinol does occur on grinding was obtained by previous workers[4], who found that sulphur dioxide trapped in the quinol crystal lattice is partially liberated by grinding.

The large dielectric absorption of quinol crystallized from water was accompanied by appreciable direct-current conductivity. This was also observed in the samples obtained from ethanol and methanol respectively. Quinol crystallized from methanol gave an initial conductivity about 5,000 times larger than that of the other samples. This may be related to its different structure and composition[2]. It is less compact, and its crystal lattice contains entrapped methanol molecules which would escape on grinding and possibly take part in hydrogen-bond chain formation. High direct current conductivity has been reported by previous workers with other hydrogen-bonded structures, and is considered to be due to combined proton transition and dipole rotation[5].

The sample disks were measured between mercury electrodes. Bridge methods were used at frequencies greater than 1 c./s. At lower frequencies the dielectric loss factor was calculated from the anomalous charging current measured at different times after the application of a D.C. potential[6].

Spectra of Flames burning with Oxides of Nitrogen

We have taken spectrograms of pre-mixed gas flames of hydrogen, ammonia, carbon monoxide and hydrocarbons burning with nitrous oxide, nitric oxide and nitrogen dioxide, respectively. The overall spectra of the hydrocarbon flames are very similar. CH-, CN-, NH- and OH-bands are present, and so also are the C_2-bands. The latter are quite strong in many flames (especially acetylene), but are generally weaker than the C_2-bands in hydrocarbon – oxygen flames. We found no evidence of the CO-fourth positive bands in any of these flames, however strongly our plates were exposed. This band system was reported by Behrens and Rössler[1] in a benzene – nitric oxide flame. In the region of the spectrum where this band system of CO should occur, we obtained strong NO-γ-bands.

The flames of hydrocarbons burning with nitrogen dioxide have a double inner cone. The first inner cone emits a continuum of yellow light, and the second, which is separated from the first by a dark space, emits blue light containing C_2-, CH-, CN-, NH-, OH- and NO-bands. In absorption spectra, the NO_2-bands disappear in front of the first inner cone, and if benzene is taken as the fuel, the ultra-violet bands of benzene disappear at the same position as the NO_2-bands. NO-γ-bands appear in absorption in the first inner cone and disappear again in front of the second inner cone. There is no doubt that both nitrogen dioxide and benzene decompose in the first inner cone. Some interaction between them also occurs, as it is possible to adjust the flame in such a way that the second inner cone blows off and the first cone burns alone, though with diminished flame velocity. Under these conditions a large amount of nitric oxide can be detected in absorption in the exhaust gases. This is normally consumed in the second inner cone.

The hydrogen – nitrogen dioxide flame has only one inner cone, and burns more rapidly than a saturated hydrocarbon flame with nitrogen dioxide. It seems that the nitrogen dioxide readily decomposes in the flame, and that the subsequent reaction of hydrogen and oxygen is sufficient to account for the high flame velocity. Nitric oxide does not seem to participate in the reaction, and consequently the flame does not reach its theoretical temperature. This is confirmed by various observations; for example, the OH-emission from the inter-conal gas is only about one-hundredth of that of a hydrogen/oxygen flame.

The hydrogen – nitric oxide flame has a very low speed, although it has a higher temperature than the hydrogen – oxygen flame, which is very fast. Thermal decomposition of nitric oxide is probably the rate-determining process. This decomposition is very slow and will only take place at very high temperatures. The process is feasible in the hydrogen – nitric oxide flame because the velocity is low and sufficient time is available.

In contrast to the hydrogen flame, the ammonia – nitric oxide flame burns readily and with a greatly increased flame speed. Strong NH-bands are emitted which scarcely appear in the spectra of the hydrogen flame. The presence of this radical may be responsible for the different behaviour of the ammonia flame. NH-radicals may be able to decompose nitric oxide and provide an alternative path of low activation energy for the production of oxygen. Hydrocarbon – nitric oxide flames have velocities which increase in the same order as the increasing C_2-, CH- and NH-band strengths, and it seems that nitric oxide again decomposes by radical reactions.

We are indebted to the Chief Scientist, Ministry of Supply, for permission to publish this communication.

A New Method for Measuring the Atomic Heats of Gases

In a previous communication in *Nature*[1], a method was described by which the atomic heats of various gases could be determined from the aspects of heat transfer through the gas. The method has recently been modified to take into account the dependence of the accommodation coefficient upon the pressure of the gas at very low pressures.

In the absence of convection, the rate of heat loss Q corrected for radiation from a uniformly heated thin platinum wire lying along the axis of a cylindrical tube can be represented in terms of the gas pressure P by an equation due to Knudsen and others in the form:

$$Q = 2\pi r_1 LP\,(R/2\pi MT_2)^{1/2}(\beta + \tfrac{1}{2})\alpha_P(T_1 - T_2), \qquad (1)$$

in which the mean collision path is greater than, or comparable with, the distance between the wire and the internal surface of the tube. In (1), βR represents the molecular heat of the gas, α_P the coefficient of accommodation, T_1 and T_2 the temperatures of the wire and tube surfaces respectively, r_1 the radius and L the length of the wire, and M the molecular weight of the gas.

Values of α_P calculated from (1) at very low pressures are found to vary considerably with the pressure up to the region in which the temperature-drop effect operates and throughout which the values of α_P are independent of the gas pressure. In this latter range of pressures the modified Fourier's relation is represented[2] by:

$$\frac{1}{Q} = \frac{\log (r_2/r_1)}{2\pi r_1 KL\theta} + \frac{1}{P\theta A}\left(\frac{T_1{}^{1/2}}{r_1} + \frac{T_2{}^{1/2}}{r_2}\right), \qquad (2)$$

where the term A is defined by:

$$A = \frac{R^{1/2}2\pi\,(\beta + \frac{1}{2})2\alpha L}{(2\pi M)^{1/2}(2 - \alpha)}.$$

If the temperature of the wire is kept constant over both ranges of pressures, and if α_P is known as a function of pressure and temperature, β can be calculated. Equation (1) must be modified, using the Langmuir adsorption equation:

$$\theta/N_0 = bP/(1 + bP),$$

where θ denotes the number of lattice spaces per square centimetre of the wire surface which are occupied by gas molecules at a pressure P and temperature T, and N_0 denotes the total number of lattice spaces per square centimetre. The effect of accommodation may be considered as being due to the extent to which the lattice spaces are occupied by molecules. Hence we may write for α_P, following Amdur[3],

$$\alpha_P/\alpha_\infty = \theta/N_0 = bP/(1 + bP), \qquad (3)$$

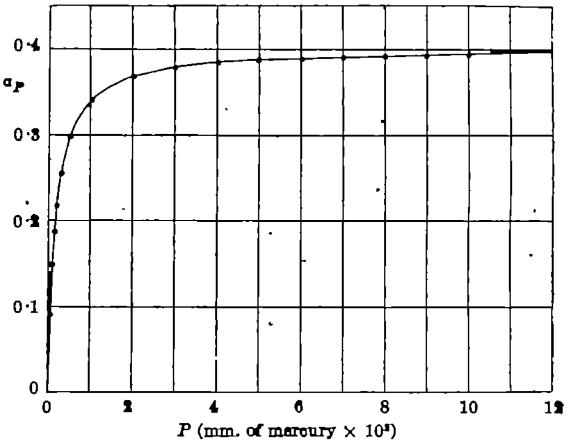
where b is a function of temperature and α_∞ denotes the coefficient of accommodation over the temperature-drop range of pressure.

Equation (1) may now be written in the form:

$$\frac{P^2}{Q} = \frac{1}{2\pi r_1 L(R/2\pi MT_2)^{1/2}(\beta+\frac{1}{2})\alpha_\infty(T_1-T_2)}\cdot\left(\frac{1}{b} + P\right),$$

from which P^2/Q is found to satisfy a linear relation with P. At the same time, $1/Q$ has been found to satisfy a linear relation with $1/P$ over the temperature-drop range of pressure at the same wire temperature as in (1).

It is therefore possible to determine β and α_∞ and also a value of b. The accompanying graph shows the variation of α_P with P as quoted from equation (3) by the substitution of α_∞ and b for hydrogen at a wire temperature of 19° C. From the graph it appears that α_P rises very sharply with P at very low pressures. The table shows observed values of α_∞ and β for a number of gases at laboratory temperatures.



Gas	H_2	N_2	O_2	He	Ne	A
β	2·49	2·50	2·49	1·49	1·49	1·50
α_∞	0·40	0·81	0 80	0·42	0 78	0·84

The method has also recently been applied in order to investigate the decrease of the rotational energy of hydrogen, oxygen and nitrogen at very low temperatures.

It is hoped to publish a detailed account later.

Quantitative Paper Chromatography

Fisher, Parsons and Morrison[1], discussing quantitative paper chromatography, found an interesting relationship between spot-length or spot-area and the logarithm of spot content for certain amino-acids and the sugars xylose and arabinose. They suggest that the relationship may be of general applicability to sugars.

Using Longenecker's method[2] for ascending chromatography (somewhat modified), with 500-ml. and 1-litre jars and papers 5 mm. wide, measuring spot-length instead of spot-area, an attempt has been made to confirm this work using saturated *n*-butanol–water mixture (water-poor phase) as solvent and sucrose as the sugar. Spraying was carried out with the phloroglucinol reagent mentioned by Horrocks in his paper[3]. Spot-length instead of spot-area was chosen for measurement because maximum elongation can fairly easily be measured with practice on narrow papers, and the work was intended for rapid assessment of quantitative differences. Sucrose was chosen in preference to xylose or arabinose for investigation, because it is of more interest in studying the nutritional requirements of plants and gives a clear yellowish-brown stain on a very pale background with phloroglucinol spray.

It has been found that for a spot-content of more than 100–250 µgm. of sucrose (depending upon the conditions mentioned later), the linear relation between spot-length and logarithm of spot-content breaks down, and a much truer representation is found by the logarithm of spot-content bearing a linear relation to the *logarithm* of spot-length. This has been tested and found to hold true over a range 4–450 µgm. of sucrose. It may be noted that at low concentrations of sugar, either the logarithm of spot-length or spot-length itself will tend to give a linear relation with the logarithm of spot-content.

In addition, an investigation of the factors determining the length of stain has been attempted, and there are indications that increase of temperature decreases absolute stain-length while increase in the time of running of the chromatogram has the opposite effect. Increase of the time allowed for equilibrium to be reached before running the chromatogram also increases absolute stain-length. For all the combinations of controlled temperature (35–40° C.), length of run, and time of equilibrium so far tested, the graphs of logarithm of stain-length against logarithm of spot-content have been parallel within the limits of experimental error. On the subject of slow attainment of equilibrium conditions, the recent paper of Müller and Clegg[4] can be consulted.

This work has been carried out as part of the programme in plant physiology of this Section. It is intended to publish a fuller account elsewhere.

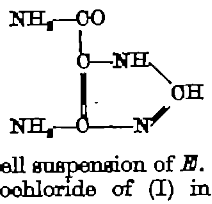
Ribosidation of 4-Amino-imidazole-5-carboxamide by *Escherichia coli*

It has already been shown[1,2] that 4-amino-imidazole-5-carboxamide (I) is a precursor of the purines in *E. coli*; a purine-requiring mutant of the organism grows in a medium containing this substance. On the other hand, it has been observed[3,4] that synthetic 4-amino-imidazole-5-carboxamide is little utilized by a growing culture of *E. coli*. The following observations will eliminate this apparent discrepancy.



(I)

(1) When a cell suspension of *E. coli B* is incubated with the hydrochloride of (I) in *M*/15 phosphate buffer (*p*H 7), and the supernatant is added to the purine-requiring *E. coli* mutant, a growth-enhancing effect is observed which is five times as great as that of the hydrochloride of (I).

(2) The supernatant containing the new factor was lyophilized and the concentrate subjected to paper chromatography according to Carter[5] in 5 per cent potassium dihydrogen phosphate – *iso*amyl alcohol and developed by diazotization. Incidentally, the presence of the original amino group in the new factor was thus established. While the hydrochloride of (I) has R_F 0·68, a new spot of R_F 0·63 was observed. The activity of the new spot was established by the bio-autographic technique of Winsten and Eigen[6].

(3) The fraction containing the new substance showed a positive orcin test and a colour reaction with diphenylamine[7] which exceeded that of the blank, indicating the presence of deoxyribose. The ultra-violet spectrum showed a shifted absorption maximum (2600 A.) as compared with the hydrochloride of (I) (2680 A.).

It seems thus established that 4-amino-imidazole-5-carboxamide is converted by *E. coli* into a glycoside.

(4) It has not been finally established whether the new substance is a nucleoside or a nucleotide. According to Carter[5], nucleotides cannot be chromatographed by means of butanol. Since the new spot could also be obtained in butanol, it seems likely that the new substance is a nucleoside (deoxyriboside of (I)). A similar substance may have been encountered by Friedman and Gots[8] in their recently reported experiments.

(5) In connexion with the mechanism of the conversion of (I) into purine bases, the following observation appears to be of interest. When (I) is added to a cell suspension of *E. coli* in phosphate buffer (*p*H 7) containing 0·2 per cent glucose, the diazotizable amino group disappears, and a substance is formed which has the activity of a nucleoside (it is eight times as active a growth factor for the purine-mutant as the hydrochloride of (I)). It appears that the catabolism of glucose can supply to the glycoside of (I) the C_2 atom of the purine system[9,6].

The question has often been asked[9] whether (I) is utilized as such or in the form of a glycoside. From the observation made here, and those reported recently by Greenberg[11] and by Schulman and Buchanan[12] for pigeon's liver preparations, it seems that the purine bases are formed via their ribosides and ribotides, and that in (I) the pyrimidine ring is closed only after ribosidation has occurred. According to S. E. Kerr *et al.*[13], however, adenine and guanine are incorporated by rapidly growing yeast into ribonucleic acid much *better* than the corresponding nucleosides and nucleotides.

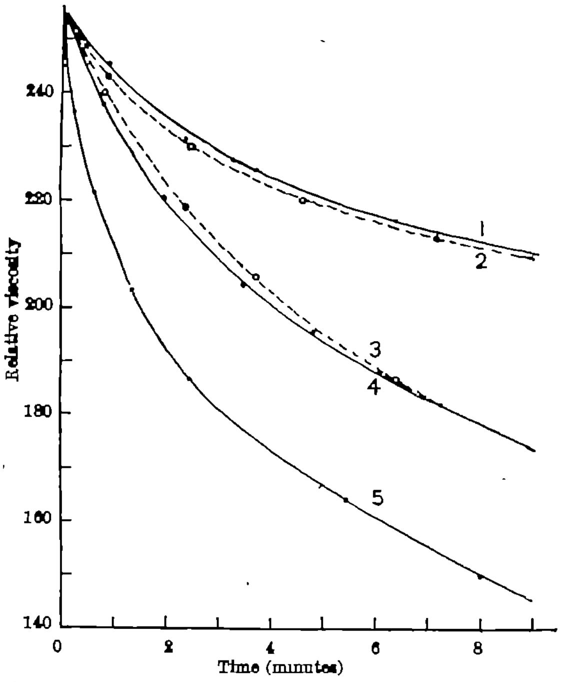
Effect of Histamine on the Activity of Hyaluronidase

M. Fabinyi and J. Szebehelyi[1] have reported that histamine neutralizes the inhibition of hyaluronidase with heparin. We had already dealt with the problem of the influence of histamine on the system hyaluronic acid – hyaluronidase – hyaluronidase-inhibiting agents. Since we had not observed any effect of histamine at that time, we decided to repeat our investigations. Unfortunately, the communication by Fabinyi and Szebehelyi gives no information as to the source of their hyaluronic acid and hyaluronidase, or the concentrations used in their investigations; and we have received no reply to a request for further information.

In our latest investigations we used as substrate highly purified hyaluronic acid (from umbilical cords) as well as a fresh, watery extract from umbilical cords. A hyaluronidase preparation by Armour Laboratories, Chicago, and a testicular extract from guinea pigs were used as enzymes. As inhibitory agents we used partly heparin (Hoffmann–La Roche, Basle) and partly fresh human serum. Viscosity measurements were carried out with a viscosimeter of the Ostwald type at a temperature of 37° C. McIlvain's citrate buffer, together with sodium chloride, *p*H 7·0, were used as solvents. The concentrations of heparin and serum were chosen with the view of producing a distinct, but not complete, inhibition of the hyaluronidase.

We find that the time-curves for the reduction of hyaluronic acid in the presence of heparin and histamine (the latter up to 20 mgm. per cent) coincide with the control without histamine. Histamine *in vitro* has therefore no marked influence on the system hyaluronic acid – hyaluronidase – heparin.

According to Swyer[2], there is also *in vivo* merely an additional effect but no reciprocal action between hyaluronidase and histamine.



Decrease of viscosity of a solution of hyaluronic acid by means of hyaluronidase. Curve 1, with heparin (8·5 mgm. per cent); curve 2, with heparin (8·5 mgm. per cent) and histamine (14·7 mgm. per cent); curve 3, with heparin (2·1 mgm. per cent) and histamine (14·7 mgm. per cent); curve 4, with heparin (2·1 mgm. per cent); curve 5, without heparin and histamine

We conclude that Fabinyi and Szebehelyi's view that histamine causes an enzymatic depolymerization of tissue mucoids by favouring the action of the hyaluronidase, inhibited by heparin, is untenable.

Response of the Isolated Rat Diaphragm to Repeated Stimulation

Gans and Miley[1] showed that skeletal muscle of the adrenalectomized animal is easily fatigued *in situ*. Ingle[2] used this property of the adrenalectomized rat as a basis for the assay of cortical hormones, and he has more recently shown[3] that cortisone also increases its resistance to fatigue. Schweitzer[4] attributed this readiness to fatigue to a fall in blood pressure due to the loss of the adrenals. The fatigue has also been attributed in part to impaired neuromuscular transmission[5], but Walker[6] opposes this view.

The response of the isolated rat diaphragm to frequent stimulation through the phrenic nerve, and the effect of cortisone and of deoxycorticosterone acetate on this response have been investigated. Normal and salt-treated adrenalectomized rats of about 150 gm. were used.

Phrenic nerve-diaphragm preparations, suspended in Krebs's solution (with 5 mgm. calcium ions per 100 ml.) at 38° C. through which a gas mixture of 95 per cent oxygen and 5 per cent carbon dioxide was bubbled, were stimulated through the nerve to give a maximal response with a current duration of 200 µsec. at a frequency of 12/min. After a steady height of contraction had been reached (1–2 hr.), the rate of stimulation was increased to 2/sec. for 5 min., and then restored to 12/min.

In the preparation from normal rats, the twitch tension immediately after the 'fatiguing' stimuli was usually about 68 per cent of what it was immediately before. Experiments carried out throughout the day at intervals gave similar results. After a period of rapid stimulation, the twitch tension never recovered its original height unless the fluid in the bath was replaced; even then recovery was usually incomplete. Similar preparations from adrenalectomized animals gave similar results (see table; cf. Ramey *et al.*[7]).

The effect of adding cortisone or of deoxycorticosterone acetate to the bath fluid was tried. Four separate experiments, as described above, were carried out on each preparation, the periods of rapid stimulation (2/sec.) being separated by an interval of 1 hr. The bath fluid was changed after each experiment.

PER CENT DECREASE IN TWITCH TENSION DUE TO RAPID STIMULATION (2/sec. for 5 min.)

	Exp. 1 control	Exp. 2 with drug	Exp. 3 control	Exp. 4 with drug
Normal	32	34 *C*	31	44 *C*
Adrenalectomized	35	35 *C*	37	34 *C*
Normal	26	24 *D*	14	25 *D*
Adrenalectomized	35	38 *D*	31	29 *D*

C = Cortisone. *D* = Deoxycorticosterone acetate

About 30 min. before the second and fourth experiments, the drug to be tested was introduced into the organ bath. The solutions of cortisone and of deoxycorticosterone acetate were prepared by diluting the proprietary preparations (Merck and Co., and Dale respectively) with 20 per cent alcohol, so that 1 ml. contained 500 and 100 μgm. of the drug respectively. The volume of fluid in the bath was 55 ml. 1 ml. of 20 per cent alcohol had no effect on the twitch tension. The results show that the drugs did not influence the 'fatigue' process.

Protective Action of Methylamine against X-Irradiation

Colter and Quastel[1] have shown that many amines (benzedrine, ephedrine, tyramine, methylamine, dimethylamine, ethanolamine and histamine) act as competitive anticholine oxidases, and protect choline oxidase against the inactivating effect of nitrogen mustard. It is well known that irradiation with X-rays has many effects in common with mustards. Accordingly, we tried the least toxic of these amines as protector in mice against a lethal dose of X-rays.

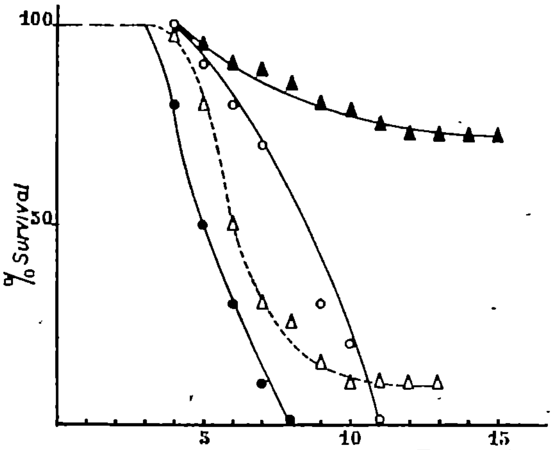
Mice of pure breed (C 57 black), four to six months old, were exposed to X-rays in groups of ten, in a cardboard box 10 cm. × 10 cm. Physical constants: 250 kV., 18 mA., copper filter 0·25 mm., focal distance 50 cm., field 150 cm.², mean output 90 r./minute.

A first control group of mice received a single lethal dose of X-rays. A second group was injected intraperitoneally with methylamine (2 mgm.) neutralized in water solution; this dose is well tolerated. A third group was irradiated just as the controls, immediately after an intraperitoneal injection of 2 mgm. methylamine.

Forty controls received either 700 r. or 850 r. All the mice irradiated with 700 r. died between the fifth and the tenth day after irradiation; those which had received 850 r. died between the fourth and the eighth day.

In the group of fifty animals injected and irradiated with 700 r., the mortality (from the fifth to the twelfth day) was small; 73 per cent of the animals survived (see graph).

The mice injected with methylamine and irradiated with 850 r. died between the fourth and eleventh day, later generally than the controls; only 7 per cent survived. An injection of 2 mgm. or 2·5 mgm. of methylamine did not protect any animal against a dose of X-rays greater than 850 r. A dose of 2 mgm. methylamine injected 5 or 15 min. after the end of the irradiation (700 r.) shifted the mortality curve slightly to the right.



○, 700 r.; ▲, 2 mgm. methylamine and 700 r.; ●, 850 r.; △, 2 mgm. methylamine and 850 r.

Thus, just as it has been shown with sodium cyanide and sodium azide[2,3], the action of methylamine is one of pure protection: the substance must be present in the body during the irradiation; it becomes ineffective if given after irradiation.

Our observations offer a new fact in favour of the similarity of action of mustards and X-rays, which has been emphasized recently (for a review, see Bacq[4]).

Protective Action of Ethyl Alcohol on Irradiated Mice

EARLIER unpublished work on the effects of ethyl alcohol on cells *in vitro* suggested to us the possibility that alcohol might modify the response to X-rays. With the present-day interest in agents which may modify the systemic effects of radiation, it was thought worth while to carry out experiments on the influence of alcohol on the lethal effects of whole-body irradiation in mice.

Pure-bred mice of the "A" strain six to eight weeks old were used. In a preliminary experiment, ethyl alcohol was diluted with saline to a concentration of 10 per cent by volume and the solution administered orally in two doses each of 1 ml., the first given 80 min., and the second 20 min., before irradiation. An equal number of control mice were treated similarly with saline. All the mice were then given 700 r. X-rays, a dose which is lethal to the "A" strain. The results are shown in Table 1.

Table 1

Treatment	Number dead	% Mortality
Saline followed by 700 r.	22/22	100
Alcohol followed by 700 r.	14/22	63

re extensive experiments were then carried out, as a criterion the difference in L.D.50 determ- y the probit method for control and alcohol- d mice. For this determination four or five vels were chosen which could be presumed to t the 50 per cent lethal dose for this strain of One group of alcohol-treated and one group rol mice were irradiated at each dose-level.

figures obtained in one experiment are shown le 2; they demonstrate a rise in the L.D.50 vith alcohol treatment (1·5 ml. 10 per cent , given as two doses before irradiation).

Table 2

	Number of mice	L.D.50	Stand. dev. of L.D.50
cohol	110	625 r.	13·3 r.
line	109	564 r.	8·7 r.

e difference here is highly significant ($p > 10^{-4}$). protective effect of alcohol was also examined the point of view of the lengthening of the time vival of mice which die within the time-span of periment (thirty days).

s been found from other experiments that at t and above the L.D.100 level the mean l-time of mice decreases inversely with dose. ean survival-time was calculated for two ex- ts. In one, mice were irradiated with 690 r., econd with 700 r. In the first experiment the urvival-time for saline-treated controls was ys, that for alcohol-treated animals being ys. In the second experiment the figure for was 9·0 days, compared with 12·1 days for -treated mice. The difference in both cases ificant ($p = 0·05$).

vould therefore seem that the administration hol prior to radiation increased the dose re- l to kill 50 per cent of the mice, and extended e of non-survivors.

protection was obtained when the 10 per cent l solution was given after radiation in two 1 ml. immediately after radiation followed by one hour thereafter.

parison of the protective effects of equal es of 10 per cent or 5 per cent alcohol showed both concentrations were protective, but that ifference in protection value between them was ignificant.

an attempt to compare the protective effect ohol with that of cysteine, using the same strain ice, it was found that an intravenous dose of gm. cysteine per mouse seemed to have a rather er effect than oral alcohol in the doses used. We not tried the effects of higher doses of alcohol. e protective effect of alcohol is probably un- ed to its anæsthetic effect. Although the majority ice given 1·5 ml. of 10 per cent alcohol were red unconscious, this was rarely the case for given the same volume of 5 per cent alcohol.

rthermore, we have tested two other substances sthetic doses for protection: (*a*) nembutal nously, 1·3 mgm. per mouse, (*b*) ethyl carbam- peritoneally, 20 mgm. per mouse. Neither substances altered the L.D.50. This was rprising in the case of ethyl carbamate, as been found to lessen the lethal effect of cells *in vitro*.

Microspheres of Organic Substances

SPHERICAL particles of glass ranging in diameter from about one micron upwards, which can be prepared by the method of Bloomquist and Clark[1], have found a wide range of usefulness, for example, as adsorbents of known surface area[2], as material for the study of 'fluidization' of beds of particles[3], and in electrokinetic measurements on cataphoresis and sedimentation velocity[4,5]. For many such experiments, particularly the electrokinetic ones, it would be desirable to be able to use microspheres of substances other than glass. I have found that it is possible to obtain many organic compounds in microspherical form, provided that they melt below 100° C., and are more or less insoluble in water. The substance to be used is mechanically stirred at a very high rate with thirty to forty times its weight of water, at a temperature 10–15° above the melting point of the substance, thus producing an unstable emulsion of liquid drops in water. This is then run rapidly into a large excess of cold water, producing solid spherical particles of the substance. Some degree of control over the size of particle obtained can be exercised by modifying the rate and time of stirring. In this way, microspheres of naphthalene, octadecane, *m*-dinitrobenzene, cetyl alcohol, stearin, stearic acid, and several other organic compounds have been prepared. These particles are used in the study of the electrokinetic properties of organic compounds by the method of electroviscous sedimentation[6].

Most of these particles keep indefinitely under water, but if allowed to dry off, some of the softer ones tend to lose their shape. Some aggregation may also occur on drying, and the particles are then difficult to redisperse, so that it is advisable to store them under water so far as possible.

It should prove feasible to apply this method to low-melting inorganic substances, using non-aqueous liquids as dispersing media.

An Isopod, *Asellus meridianus* Racovitza, with Low Chromosome Number

IN the past fifty years, several papers have described the chromosomes of Isopoda, and the numbers for twenty-seven species have been recorded. Most of this work has been done by Vandel[1,2]. The numbers range from 6 to 60 taking the group as a whole, but some families may show less variation than others[3]:

Haploid numbers:	6,	7,	8—	16,	17—	24—	27,	28,	29,	30,	31—	34—	60
Flabellifera	1												
Epicaridea			1										
Asellota		1	3				1						
Oniscoidea			3	1	1	2	2	6		1	1	1	1
Valvifera								1	1				

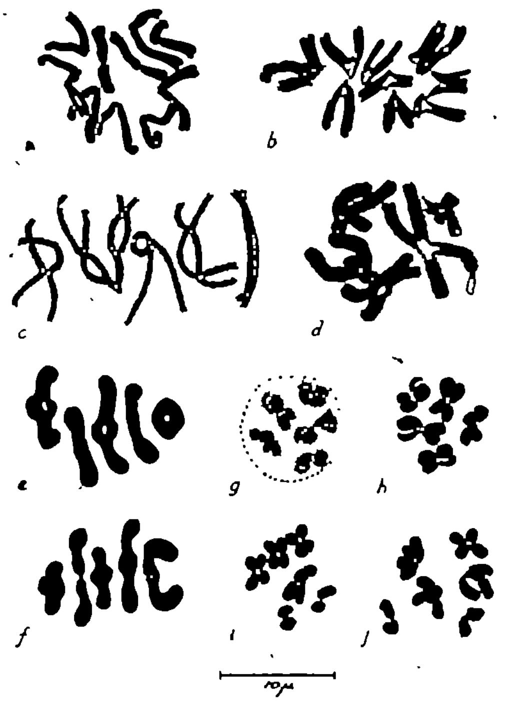
Vandel[1] has studied two species of *Asellus*, *A. aquaticus* and *A. meridianus*, both with $2n = 16$. According to him, *meridianus* has only v-shaped chromosomes and at metaphase I he finds 8 bivalents and a 'chromatoid-body'. He further states that his *meridianus* is identical with the species as it was first described by Racovitza[3].

The systematics of Asellota has become very complex in the past thirty years owing to the large number of species and subspecies described (Chappuis[4]). I therefore took great care in identifying the British *Asellus meridianus*; it corresponds in every detail with the original description by Racovitza. The chromosome number of the British *Asellus meridianus* Racovitza, however, is $n = 5$, the lowest number recorded for the Isopoda.

We are then faced with the possibility that a species has morphologically identical forms on the Continent and in England, but the chromosome numbers of which differ specifically. Since it is apparently easier to find racial differences than complete homology in this genus (Chappuis[4]), some mistake has probably been made.

The five chromosomes are median and submedian, ranging in size from 5·5 to 10 μ at mitotic metaphase. In embryonic tissue the chromosomes can be studied in detail. One chromosome pair has a terminal heterochromatic block in the short arm and what appears to be a secondary constriction in the long arm. The constriction is only clear in some cells, but a certain precocity in chromatid separation in the distal part can frequently be seen.

The heterochromatin in the short arm organizes the nucleolus. At telophase two nucleoli are formed which later fuse. Consequently, in prophase th heterochromatic ends are frequently found in imity when the nucleolus has disappeared.



(*a*) Somatic mitosis from embryo; big autosome at 9 o'clock showing split chromatids distally to secondary constriction. (*b*) Early anaphase; homologous chromosomes at 9 and 2 o'clock with secondary constrictions and terminal heterochromatin. (*c*) Diplotene bivalents drawn separately. (*d*) Diakinesis; animal heterozygous for heterochromatin. (*e*) and (*f*) Metaphase I; spermatogenesis. (*g*) Interkinesis. (*h*) Prometaphase II, normal. (*i*) and (*j*). Same; abnormal with one split univalent

It is not possible to detect any differe chromosome morphology between the embr one must conclude that no distinguishab chromosomes are present. One embryo about sixty) was heterozygous for the t heterochromatin.

In male meiosis the nucleolus persists at phase I in about 10 per cent of the cells. The c frequency appears to be about 1·7 per biva diplotene (twelve cells) and 1·1 at metaphase cells). Some caution must be exercised with to the diplotene frequency because centric p (and stickiness) is not uncommon. This is presu the reason why some chromosomes are seen tc fallen apart before metaphase II. They ma be univalents which divided at first division this is not likely since the univalent frequenc be low.

The material is very well suited for experi work, particularly with water-soluble chemic the early spring (March) the smaller fem found attached underneath the males, a which they maintain even when the embr well advanced in development. Underne female in the brood-pouch, about eighty emb found beautifully synchronized in developme brood-pouch can easily be opened and the e reared separately for experimental series. T easily penetrated by chemicals; for exa 0·025 per cent colchicine solution gives c c-mitosis after four hours.

Nature of Ovarian Dermoid Cyst F

THE fat which accumulates in the ovarian de cyst has long attracted interest. Sotnitchewsk 1880, suggested that this fat was analogous to s and since that time it has been assumed by workers that the two substances are identic assumption that receives support from the logical evidence of the presence of sebaceous g in the cyst walls. Many studies of the compo of this fat have been made[1], but these are incon and have been concerned largely with the un ifiable matter present. During the course of of the composition of human sebum[2], a supp fat from a dermoid cyst became available, opportunity was taken to compare the co of the cyst fat with that of sebum.

The general properties of the dermoid cy shown in Table 1, together with the corr figures, obtained by MacKenna, Wheatley a all[3], for human sebum. The non-saponifia was fractionated chromatographically, and are summarized in Table 2, together wit of similar studies on human sebum[4]. fractions of the dermoid cyst fat, with

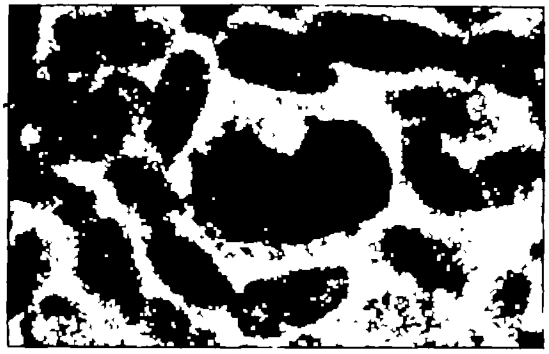
The Eosinophil Cell as seen in the Llama

THE increasing clinical use of substances of the cortisone group raises many new questions in the field of hæmatology, and it is considered that observations made in the animal kingdom, particularly in regard to the aspect and behaviour of the eosinophil cell, should help towards a greater understanding of the physiology of this cell in mammals, and therefore in the human being, and perhaps also of the problems arising in therapeutic practice.

Wishing to confirm my observations of the eosinophil cell, as seen in the camel[1], by making further investigations on an animal of the same family, I obtained, with the generous co-operation of the Zoological Gardens, London, some blood slides from the llama. The slides were stained with May–Grunwald–Giemsa, and it was expected that the red blood corpuscles would be elliptical as in the camel. Instead, however, the corpuscles were found to be much more elongated than in the camel, the length varying considerably, some red blood corpuscles being up to twice the length of others. Moreover, the granules of the eosinophil cells were also elongated, some actually appearing to be more like rods.



Peripheral blood from the llama showing the granules of the eosinophil cell, some being very elongated and rod-like. Notice in the background the different sizes of the red blood corpuscles

The llama, therefore, confirms what appears to be a rule in the eosinophils of mammals, namely, that the characteristics of the eosinophil granules bear a definite relationship to the characteristics of the red blood corpuscles in the same mammal, particularly in shape. Cases of ovalocytosis in human beings show this same relationship very clearly. This further confirmation, afforded by investigation of the llama's blood, gives added weight to my interpretation of the physiological function of the eosinophil cell as a precursor of red blood corpuscles. It should be possible to watch the cycle of red blood corpuscle secretion in the spleen of the llama with a series of eosinophil cells showing, in their cytoplasm, the growth of granules to the size of fully developed red blood corpuscles, before being shed into the blood circulation, in the same way as this has been observed in a thyroid hæmorrhagic cyst in human beings, and in the spleen of the camel.

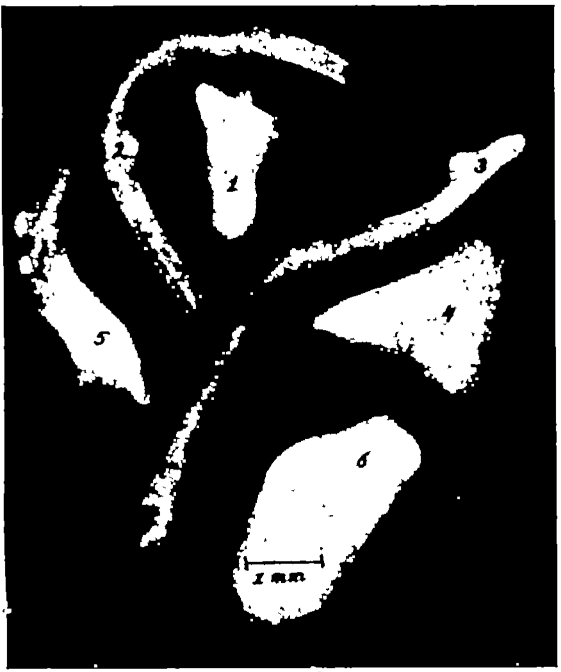
Differentiation of Skeletal Structures from Mouse Embryo Mince in the Peritoneum of Adult Mice

In the course of attempts, as yet unsuccessful, to produce a non-malignant ascites growth of undifferentiated cells in peritoneal exudate, virgin female mice of two genotypes were injected intraperitoneally with homologous embryonic tissue mince, dissociated in a Waring micro-blendor and capable of passage through a 22-gauge hypodermic needle. Embryos ranged from the 4½-mm. 13-day stage, at which condensations of mesenchyme appear at the location of the future skeletal axes, to 8 mm. in length. Each of ten hosts received an inoculum equivalent to three embryos.



Skeletal structures recovered from the peritoneum of mice three weeks after injection with mouse embryo mince.
(1) Talus; (2) abnormally regenerating rib; (3) distal portion of 9th or 10th rib; (4) head of humerus; (5) ascending ramus of pubis; (6) bone teratoma

The treated mice failed to produce ascitic fluid, such as obtained by Klein[1] with a representative variety of dissociated neoplasms. Three to five weeks after injection, all the hosts were found to contain various teratomata, islands of bone and cartilage attached to the surfaces of spleen, liver, diaphragm and mesentery, and numerous fully differentiated, anatomically defined bones, including whole ribs, phalanges, sesamoids and vertebræ, corresponding in size to the skeletal proportions of mice about one week after birth. The bony structures (see photograph) are of especial morphogenetic interest, in that they provide further evidence (similar to the *in vitro* results of Fell and Robinson[2] with chick femoral rudiments) that skeletal primordia surpass other tissues in their capacity to attain not only advanced histological differentiation, but also to continue their normal anatomical development in foreign sites. In a relevant experiment, Ephrussi[3] cultured portions of 10-day mouse embryos homozygous for the lethal brachyury gene and their normal sibs and obtained differentiation of cartilage, but no definitive bone. It remains to determine the earliest develo stage from which anatomically recognizable the skeleton may be grown *in vitro* or *in* the minimal size of fragment still permittin bone growth.

Toxicity of Copper in Solution to t Stone-loach

In June 1951, stone-loach (*Nemacheilus ba* L.), which had been kept alive in an aquariu March 1951, died when it became necessary to repl the water supply, which came from a nearby re with lake-water from Windermere. Chemical a showed that the original water contained 0·15 copper (Cu++) whereas the lake-water had 0·28 copper, presumably derived from the inflow Stone-loach, when placed in water containing in solution from nil in steps of 0·05 to 0·30 copper, lived in concentrations less than 0·20 copper, but all except one fish died within twen hours at concentrations of 0·20 p.p.m. and It seems reasonably certain, therefore, that th died of copper poisoning. This note is pub because it may be of practical interest.

An Improved Block for Spore-Formati in Yeast

V. Hartelius and E. Ditlevsen[1] recently [illegible] attention to the fact that gypsum blocks u spore-formation in yeast will not tolerate th heating necessary for adequate sterilization trials with various materials, they finally block cast of Portland cement and kieselguh after hardening in carbon dioxide is sufficient

Nearly sixty years ago, H. Elion[2] refe disadvantages of the use of gypsum block for th study of spore-formation in yeast. He stated tha he had been using for several years [illegible] size 2 cm. × 2 cm. × 2 cm., made to hi [illegible] of unglazed porcelain, and that these [illegible] could be obtained from laboratory s [illegible] can easily be cleaned, sterilized and use [illegible] Elion described the excellent results w obtained by using these porcelain blocks [illegible] of spore-formation in yeast, and during many thereafter he continued to use these blocks great satisfaction.
